INDEX

A

| | Page. | | Page. |
|---|--|--|--|
| Abangarez Gold Fields Co., Costa Rica..... | 199, 351, 671, 711, 911 | Juneau district mines | 783 |
| Ablett, C. Antony, and H. M. Lyons..... | Application of three-phase motors to winding engines and noists... 689 | Juneau in 1913 | 545 |
| Ditto..... | Choice of drum for steam or electrical drive... 774 | Ketchikan district activity | 630 |
| Abosso mine, West Africa, history..... | 1008 | Klondike gold discovery history | 1008 |
| Abrasive wheels | 423 | Land laws and report of Franklin K. Lane..... | Editorial... 91 |
| Acacia Gold Mining Co., Colorado, company report..... | 430 | Long Lake power development..... | E. P. Kennedy... 180 |
| Acadia Coal Co., Nova Scotia..... | 504 | Matanuska coal, U. S. Bureau of Mines | 708 |
| Accident Commission, California, rulings of | 337 | Matanuska coalfields | Editorial... 758 |
| Prevention, Anaconda Copper Mining Co. Editorial..... | 166 | Mine inspector's report | 944 |
| Prevention in mining..... | Edward Ryan... 498 | Mineral production in 1913 | 88 |
| Prevention, Nevada Consolidated..... | Lindsay Duncan... 288 | Nelchina district | 307, 630, 1029 |
| Accident Gold Mining Co., California..... | 825 | Noatak-Kobuk region | 787 |
| Accidental discoveries of mines | G. L. Sheldon... 454 | Nome and Grand Central region geology | 816 |
| California, 1913 | Editorial... 480 | Nome, Third Beach Line at | Arthur Gibson... 686 |
| Accidents, danger from falls of rock | 698 | Nome, trade in 1913 | 154 |
| In mines | 464 | Nome tramway | 718 |
| Industrial, under compensation, Nevada | 332 | Opportunity arrives | Editorial... 319 |
| Metal mine | Editorial... 207 | Petroleum industry | 154 |
| Metal mines in United States | 13 | Placer mining | 154 |
| Street, in Great Britain in 1913..... | Editorial... 558 | Railroad bill | 232 |
| U. S. coal mine fatalities | 1075 | Ditto | Editorial... 319 |
| Accounting, mine | 782 | Railway construction | 373 |
| Acetylene lamps for metal mines..... | Frederick H. Morley... 609 | Ruby district | 428 |
| Acid tanks, mastic lining for | 620 | Ruby district placer mining | 154 |
| Acme gold mine, Porcupine, Ontario | 905 | Seward Peninsula | 193 |
| Adams iron mine, Minnesota | 125 | Seward Peninsula gold dredging | 96, 154 |
| Additon, A. Sydney, death of | 750 | Shushana | see Alaska, Chisana |
| Aeolian Consolidated Copper Mining Co. and Columbia Copper Co., Idaho | 909 | Silver production | 88 |
| Aerial tramway, Leschen, Alaska | 265 | Speel River electro-chemical project..... | W. P. Lass... 218 |
| Tramway to Chinese coal mines..... | C. A. Tupper... 379 | Stripping frozen gravel | Editorial... 720 |
| Africa, Cape Colony, wages, 1913 | 844 | Thawing frozen ground for placer mining | Arthur Gibson... 143 |
| Gold and silver production in 1912..... | 164 | Third Beach Line, Nome | Arthur Gibson... 686 |
| Katanga, smelting of copper | 171 | United States Geological Survey investigations..... | 787 |
| Leaching copper in | Editorial... 318 | Yukon-Tanana region, U. S. Geological Survey | Bulletin... 193 |
| Natal, wages in 1913 | 844 | Alaska Ebner Gold Mines Co. assets sold at auction..... | 744 |
| Orange Free States, wages in 1913..... | 844 | Alaska Gastineau Mining Co. | 708 |
| Afterthought mine, Ingot, California, Leaching of zinc ore at the | Frank L. Wilson... 453 | Perseverance and Sheep Creek mines | 783 |
| Agitation, Air, by continuous method..... | Donald F. Irvin... 571 | Sheep Creek adit | 630, 940 |
| At Nevada Hills | L. B. Eames... 386 | Alaska Gold Mines Co. | 193, 344, 588, 628, 940 |
| Ditto | Alfred James... 624 | Company report | 783, 800 |
| Pulp | 423 | Preparatory work of | 800 |
| Slime, foaming during | F. J. Girard... 817 | Stock booming | 987 |
| Agriculturist v. miner | Editorial... 440 | Alaska Gold Quartz Mining Co. | 507 |
| Aguaescentes smelter, America S. & R. Co. | 707 | Alaska Hydro-Electro Chemical Co. Speel River project..... | 218 |
| Ahmeek Copper Mining Co., Kearsarge, Michigan..... | 88, 140, 160, 271, 349, 355, 514, 628, 676, 682, 747, 834, 1025, 1038 | Alaska Juneau Gold Mining Co. | 708, 746, 783 |
| Company report | 633 | Alaska Mexican Gold Mining Co. | 118, 232, 392, 428, 545, 588, 746, 783, 907, 1070 |
| Air agitation by continuous method..... | Donald F. Irvin... 571 | Company report | 118, 232, 392, 427, 545, 588, 746, 783, 907, 1070 |
| Blast, A small | 293 | Company report | 997 |
| Compressors, oil-driven | 918 | Cost, concentrate treatment, cyanide plant, 1913..... | 1024 |
| Compressors, turbo | 502 | Foundry | 1024 |
| Lift, Smuggler Union | Walter L. Reid... 452 | Tube-mill | 850 |
| Lifts, Deep mine pumping and | A. E. Chodzko... 136 | Alaska United Gold Mining Co. | 118, 232, 392, 428, 545, 588, 746, 783, 907, 1070 |
| Line connections and cup grease | 423 | Company report | 997 |
| Weight of cubic foot | 703 | Alaska Venture Syndicate | 787 |
| Ajax Mining Co. v. Merrill Metallurgical Co. | Editorial... 480 | Aldridge, Walter H..... | What is the matter with prospecting? 9 |
| Alabama, Birmingham district | 785 | Alexo mine, Ontario | 705 |
| Coal production | 1037 | Algoma Steel Corporation, Sault Ste. Marie, Ontario..... | 864 |
| Coke production | 928 | Algoma Mining Co., Michigan, company report | 998 |
| Gold and silver production | 8 | Alice G. & S. M. Co., Mont., v. Anaconda C. M. Co. | 1071 |
| Alameda property, Nevada | 427 | Alice Mining Co., Idaho | 789 |
| Alaska and Siberia, Gravel mining in | 185 | Alladin-Cobalt | 231 |
| Arrivals and departures, 1913 | Editorial... 479 | Allen, A. W..... | Filter-press operation... 697 |
| Bering River coal | Editorial... 878 | Ditto | Milling operations at the Eldorado Banket mine, Rhodesia 501 |
| Bering River coalfield, Mining methods | W. R. Crane... 327 | Ditto | Pressure and vacuum at altitude... 978 |
| Bonni field, lignitic coal reserves | 824 | Ditto | Simplification of gold ore treatment... 898 |
| Cape Nome, Drift mining in the frozen gravel deposits of | Arthur Gibson... 404 | Ditto | Solution control in cyanidation... 338 |
| Chisana goldfield..... | 118, 269, 479, 630, 824, 865, 944 | Ditto | Wet crushing in ball-mills... 419 |
| Chisana goldfield claim disputes | 588 | Allen, Carl A..... | Engineer's office... 472 |
| Chisana goldfield, Developments in the..... | E. F. Wann... 179 | Allie Mining Co., Gilmore, Idaho..... | 140, 160, 271, 355, 514, 676, 682, 747, 834, 906, 1038 |
| Chisana goldfield district, geology of | 659 | Allouez Mining Co., Allouez, Michigan..... | 669 |
| Chisana goldfield litigation finished | 746 | Company report | 188 |
| Chisana goldfield maps and trails | 659, 822 | Alloys, copper and aluminum | 125 |
| Chisana goldfield placers | Editorial... 797 | Alpena iron mine, Minnesota | 748 |
| Chisana goldfield, season's clean-up | 990 | Alpha mine, Jarbidge, Nevada | 236 |
| Circle quadrangle | 746 | Alta Tunnel & Transportation Co., Utah | 978 |
| Copper ore transport, Mother Lode mines | 265 | Altitude, Pressure and vacuum at | A. W. Allen... 5 |
| Copper production | 88, 154, 708 | Aluminum | Editorial... 188 |
| Dog-team race, All-Alaska Sweepstakes | 39, 193 | And copper alloys | 188 |
| Dredging | 735 | Density and rolling of | 550 |
| Dredging at Iditarod | 721 | Imports | 87 |
| Dredging costs | Editorial... 223 | Market | 86 |
| Dredging placer tin | 154, 193 | Market in 1913 | 276, 792, 950 |
| Fairbanks district | 269, 1070 | Prices | 938 |
| Fairbanks district gold production | 545 | United States consumption, 1913 | 636 |
| Fairbanks exsition in 1917 | 1070 | United States production | 792 |
| Gold nugget, Koyukuk district | 890 | Aluminum Industry Co., Germany | 710 |
| Gold placer on the Kuskokwim river..... | H. W. Reeth... 8, 88, 154 | Amador mine, Iron Mountain, Montana | 544 |
| Gold production | Editorial... 165 | Amadac Mines Co., Jalisco, Mexico | 864 |
| Hydro-electric power | 154 | Amalgamated Copper Co. | 666, 710, 954 |
| Iditarod-Innoko districts | 154 | Company report | |

| | Page. | | Page. |
|--|------------------------------------|---|---|
| Bank clearings in United States in 1913 | 163 | Boulder No. 1, Western Australia | 665, 863 |
| Barite, United States production 1913 | 846 | Bournonite | 301 |
| Barlow, A. E., death of | 1001 | Boyd-Smith, Jr., D.... Razing the Steptoe Valley stack | 694 |
| Barnes-King Development Co., Kendall, Montana, 394, 747, company report | 436 | Braden Copper Co., La Junta, Chile, 32, 55, 152, 158, 160, 263, 351, 355, 506, 514, 537, 627, 676, 834, 986, 1032, 1038, 1066 | |

EDITORIAL

Greeting

It is the Editor's privilege once a year to write directly to his readers, contributors, and advertisers a word of thanks for their support, and it is a pleasant privilege and a valued one. There is a bond between reader and Editor that grows with the years, and in the case of the *Mining and Scientific Press* it is pleasant to know that the tie is close. Despite the admittedly bad year and the disturbed conditions in Mexico which have forced economies in the budgets of many mining men, 'stops' have been less than had been anticipated, and the total number of paid subscribers to the *Press* has been steadily increasing since April.

If less immediately profitable than some of its predecessors, 1913 has been an unusually interesting one to members of the editorial staff. Early in the year it was found possible to carry out long-cherished

plans for opening an editorial office in New York, and Mr. Read, hastily packing his dictionary and thesaurus, left for the city on the Hudson. The move has proved a wise one in that it has made possible a marked improvement in the paper. To take Mr. Read's place in San Francisco, Mr. E. H. Leslie came up from Mexico, where he had been doing excellent work on the staff of our interesting southern contemporary, the *Mexican Mining Journal*. About the same time Mr. Gelasio Caetani joined our staff of Special Contributors and began to furnish those delightful essays in which sound technical knowledge is so mingled with homely common sense, that there have been many calls for more. Late in the year Mr. Frederick H. Morley came down from the mountains of Colorado to give to the readers of the *Press* from his store of experience and observations.

Attentive readers will have noted the large space devoted this year to flotation and copper metallurgy. Both subjects have been big with interest, and both promise much for the future. It will be the effort of the Editors to continue to print the most accurate information on these subjects and to give to the *Press* the same peculiar standing on these lines that it already enjoys in matters of cyanidation and dredging, to mention only two of what may be called *Press* 'specialties.' In this and all our work we shall strive to continue to win and to hold the confidence of readers, contributors, and advertisers. Service is the keynote of success in journalism as in other industries, and service has ever been the purpose of the *Mining and Scientific Press*.

Gentlemen, on behalf of my associates as well as myself, we thank you for your support and wish you all a happy and prosperous new year.

H. FOSTER BAIN.

January 1, 1914.

L EAD, nickel, and tin smelting have shown few changes in the year, and little of technical importance has transpired. In the Sudbury district the Mond Nickel Company began smelting at its excellent new plant, and is experimenting with Dwight-Lloyd sintering machines. The Canadian Copper Company is achieving excellent success in using powdered coal for fuel and in other lines. At the Tooele plant of the International Smelting & Refining Company, in Utah, a curious accident resulted in an explosion which destroyed the dust-chamber. It seems that when wet ore high in sulphur is put through the sintering machines, there is a reaction not unlike that which is counted on to make the Hall process of fume treatment a success—that is, a part of the sulphur comes down uncombined in the solid state. This being carried over into the dust-chamber, led to an explosion, and has also caused serious loss by fire in the bag-house. At Murray there have been murmurs of discontent and a renewal of agitation over fume trouble, and a determined effort was being made during the

year to reorganize the farmers for further action against the smelters.

D IAMONDS form one sort of an index of trade conditions, and it is interesting to read in recent correspondence from South Africa that slackness is chiefly felt in the market for small stones, indicating the effect of fluctuating demands of fashion rather than a lack of buying power the world over. The same correspondent discloses the fact that diamond dealers have a jargon all their own, as the following illuminating remarks will show: "Kimberley was freely sold this week by the Syndicate, New York buying all the closed goods. Wesselton is announced to be shown on Monday; applications for sights are numerous."

M ANY of our readers may not know of the existence of the American Museum of Safety in the Engineers' building, which houses the American Institute of Mining Engineers, since its publications are not numerous and do not reach a wide field. The influence of the Museum is widespread, however, and we recently referred to the First International Congress of Safety and Sanitation, held under its auspices. Scarcely less important is the First International Exposition of Safety and Sanitation now in progress in the Grand Central Palace, New York. Not only the makers of safety appliances have displayed their wares, but the large industrial corporations have made impressive exhibits of what they are doing to conserve the safety, health, and mental well-being of their employees.

Annual Reviews and Statisticians

In presenting this number of the *Mining and Scientific Press*, a word or two of explanation may be permitted. The change in the size of the page has been made, in part to conform to what is rapidly becoming the standard size for technical journals, and in part to permit a better use of space in connection with illustrations. Incidentally, improvements have been made in dress and style, and others are in contemplation. It will be noted that in this review much less space has been devoted to statistics than has been customary, and that there are no summaries of developments by states and districts. It is felt that this is in line with the general purpose of the *Mining and Scientific Press*, which is, to print the best technical journal of mining. The news of the mines is printed week by week. To rehash this for an annual summary is a thankless job of doubtful utility. For those far countries where periodical reviews are more appropriate as also more feasible than a steady stream of news letters, we shall continue, as in the past, to print general résumés as opportunity serves. In our Special Correspondence last week we published such letters concerning mining in 1913 in New Zealand and Rhodesia, and we expect to print, when the data are

available, another of those excellent general reviews of the progress of mining in the Belgian Congo, of which Mr. S. H. Ball has already furnished three. To be truly valuable, such summaries must be written by the right man, and when the right material has been assembled. To attempt a complete review of the world of mining at the end of an artificial period, leads but to a dreary sea of words. News of development is only news when fresh, and from eight to nine pages is set aside in each weekly issue of the *Press* for printing of significant news while it is news.

Technological developments take place regardless of calendar years. At times the progress is rapid, again it is slow. In the year that has just closed, there has been intense interest in copper smelting, and many improvements have been made or proposed; lead smelting has seen few changes. In the following pages, therefore, will be found an elaborate review of copper smelting, and only a paragraph on lead smelting. Next year, possibly, the conditions will be reversed. This illustrates the controlling motive in the selection of the material in this, as we believe, our best Review Number. Why take ten pages to say that nothing happened?

As for statistics, we print those which are available and authoritative, and will print more as they become available. A little statistical knowledge, however, is a dangerous thing. Since the fall of Adam there have been statisticians in the world, and yet even now there is no agreement as to when that interesting event transpired. A baby when born weighs perhaps eight pounds and at the end of the year possibly three times as much. At the same ratio he should weigh a trifle less than a ton at the age of five—but he doesn't.

Our Contributors

It is always a pleasure to be in good company, and the members of the editorial staff feel especially honored by those who have given of time and effort to make this number of the *Mining and Scientific Press* interesting and valuable. It is a rare pleasure to come into contact with significant men, and it is even more of a privilege to have their help. To the symposium upon the condition and needs of prospecting, of which we print a part this week, men of the widest experience and of well proved ability have contributed. Messrs. W. H. Aldridge, Philip Argall, F. W. Bradley, P. R. Bradley, D. W. Brunton, Albert Burch, George E. Collins, David Fasken, Charles Hayden, D. C. Jackling, Hennen Jennings, B. B. Lawrence, E. J. Longyear, J. H. Mackenzie, H. C. Perkins, M. L. Requa, Arthur Thacher, B. B. Thayer—and these form but a part of the list—are men who know; and what such men say may not be disregarded.

They, and those who have written the special articles in this issue, are too well known to require introduction to mining engineers, but for the benefit of the young men, and those to whom the *Press* comes

for the first time, we may say that Mr. Archibald Douglas is a busy attorney in New York who still finds time for public service of the sort with which his name is so closely associated through the activities of Dr. James Douglas. Of the presidents of the three great mining engineering societies who write for us, Mr. Rand is also president of the Spanish American Iron Company and has been active in the development of the resources of that island, as he has been in Institute affairs through the whole of his notably successful year as president; Mr. Chance, a Philadelphia mining engineer widely experienced in the problems of coal and iron, was, as much as anyone, the founder of the Society of which he writes; Mr. Scholz is engineer for, and president of, the various Rock Island coal companies, and a man who has given much time and thought to the organization of the bituminous coal operators. Mr. Rickard, who reviews the whole world of mining from the London viewpoint, finds time for the *Press* despite his duties as editor of *The Mining Magazine*. Mr. Burton is mining editor of *The Annalist* in New York, and former New York correspondent for the *Mining and Scientific Press*. Mr. Garrison is a Philadelphia engineer well known to our regular readers as one of our special contributors. Mr. De Wolf is director of the State Geological Survey of Illinois and secretary of the Association of State Geologists, of whose work he writes. Mr. Hall is a 'Tech' man who looks after the interests of the United Zinc & Chemical Company and knows the zinc business from many angles. Mr. Janin is the worthy successor to the great name among mining engineers built up by his father, brother, and uncles. Mr. Stoughton is the versatile secretary of the American Institute of Mining Engineers, who always does three men's work and then finds time to help anyone who needs help. Mr. Leslie is assistant editor of the *Press*. Mr. Denny is one of the two famous brothers who saw so far and so truly into the future of the Rand that they became unpopular there, and more recently in Mexico, London, and elsewhere have enjoyed seeing others coming to their own conclusions. Mr. Read is New York editor of the *Press*. Mr. Roush is associate editor of that very excellent journal, *Metallurgical and Chemical Engineering*, and has done us the rare favor of contributing generously to a contemporary. Mr. von Bernewitz is assistant editor of the *Press* and has brought to the study of American problems in milling several years' active experience at Waihi and Kalgoorlie. Mr. James is the London metallurgist whose worldwide interests keep him especially well informed, and whose keen comment always stimulates discussion. Mr. Peele is professor of mining at Columbia University. Mr. Austin, formerly professor of metallurgy at Michigan College of Mines, is now in general practice at Salt Lake City. Mr. Walker is our London correspondent. Mr. Searls is assistant city attorney of San Francisco and obtained his knowledge of mining law through service in Judge Lindley's

office. Mr. Dennis is a California mining engineer who has developed and managed quicksilver properties in Texas and Nevada. The writer of our New York Metal Review is a professional correspondent who devotes his whole time to watching the metal market but who prefers to remain anonymous. Even this does not entirely complete the list, since in arranging for the papers printed, and in revising and criticizing them after submitted, the members of the regular staff have had invaluable assistance from many other members of the profession.

The Mexican Crisis

The past year in Mexico has been one marked by political turmoil and general depression and one in which the mining industry has suffered keenly. As it closed, the situation showed no signs of improvement, and the immediate future holds little of promise. The Huerta administration, which when inaugurated gave promise of a solution of Mexico's difficulties, has degenerated into a military despotism. It has been accepted by but a small part of the population and its orders carry but little weight outside of the Federal District.

The period which Mexico is passing through today, and the problems and difficulties which confront the Mexican people, are those inherent in reconstruction, and as it is a long step from Porfirian despotism to democracy, those who have interests within the confines of Mexico can but abide the time when a renaissance of political and social standards will result in that longed for peace and stability of government without which no country can prosper. With Mexico, reconstruction, because of the character and status of the population, without outside assistance must be necessarily slow. Of the 15,000,000 inhabitants 80 per cent are Indians or belong to the peon class; a population which in the past has been herded, driven, and exploited by the upper class with which it has no bond of sympathy. The peon has had no opportunity to acquire property, to better his condition, or to improve his surroundings. It is to the peon, who is awakening to a realization that he is a part of the nation, that the present upheaval is due. It has been estimated that in this vast country comprising 767,000 square miles, an area equal to 17 Pennsylvanias, all of the arable land is held by 7000 families. One single landlord holds 16,000,000 acres, an area one-third the size of Great Britain, and this has been assessed for taxes at \$200,000. While a good part of those who are at present bearing arms on the revolutionary side of the struggle should be classed as bandits rather than patriots, their present position in the ranks of the revolutionists is largely due to an unhealthy political atmosphere and its direct results upon their manner of existence.

The past year has seen the overthrow of Francisco Madero, a man of undoubtedly high political ideals, but one who lacked those attributes of leadership and

organization which are prerequisite at this time. In the usurpation of power by Victoriano Huerta, it was hoped that the substitution of a rigorous policy backed by the support of the army would restore peace and put a quietus upon the disturbing element. This also has failed, and the results of another attempt at despotism has been revolution, federal bankruptcy, brigandage, general depression, and little semblance of authority. There are some who hold that with adequate funds, Huerta's policy would succeed, but in the light of his conduct of office during the past few months, this may be doubted. In fact, the estrangement between federal and revolutionary factions has increased and the resultant loss of confidence in Huerta by his previous supporters and foreign nations, augurs poorly for any solution at his hands. Mexico will not again submit to a dictatorship like that of ex-President Díaz or the present incumbent Huerta, and he who succeeds must learn as Porfirio Díaz, realizing his own shortcomings, recently stated, "that to govern Mexico, there is only one course to take and that is to act for the people and through the people." While the bestowal of an effective political franchise upon those who are not fitted to receive it is not essential, those rudiments of justice and republican government which have found so little place in Mexico to date, must receive consideration in the solution of the present situation. It is to be noted that the two important revolutionary movements, headed by Madero and Carranza have had their origin in the north; in that part of Mexico adjacent to the United States where the Mexican people have had opportunity to see the results of true democracy. It may be objected that the restlessness and ignorance of a large percentage of the people make the situation hopeless and that the form of government is of a very secondary importance; but even granting this, there is only hope for peace in a government which has been legally constituted and is identified with the majority. Only such a government can find favor with and command the respect and support of the nations.

The mining industry in Mexico has had a bad year, due largely to the interruption of railway communications and disturbed conditions which have made impossible the operation of a large number of the properties. Railway communication between the interior and the American border was interrupted early in the year and attempts to reestablish it have been futile. With the fuel oil supply from the Tampico fields intercepted, there is little hope of an early resumption of railway traffic. The coal supply has also been curtailed by the dynamiting of a number of mines by the 'revolutionists' in the state of Coahuila and interruption of railway communication.

Most of the larger silver districts, however, have kept up and in some cases increased their production. Among these may be mentioned El Oro, Pachuca, Guanajuato, and Hostotipaquillo. The returns reported for the last fiscal year ended in July show the exportation of gold to have decreased \$10,313,687; and ex-

clusive of coined silver there was a decrease in silver exports of over \$7,000,000. Copper has not fared so badly. The Cananea mines have been in practically continuous operation, as have those at Boleo and Aire Libre; the Moctezuma company reports the best year in its history. The copper exports for the fiscal year totaled \$36,522,115, which is an increase of \$3,020,242 over the preceding year. Lead showed a decrease of \$1,111,811 and the zinc exports have dwindled to \$536,094. The importance of the petroleum industry is increasing as is the output. The production for the year was estimated at 3,955,228 tons, an increase of 1,435,218 tons over that of the preceding year. The total investment in the oilfields is now estimated at \$700,000,000. Taking oil into account, the value of the mineral exports for the year showed an increase of \$3,441,807. This figure includes the silver coin exported, which was valued at \$9,806,402.

The figures presented, while showing a material decline, are evidence that mining is still being profitably conducted regardless of revolutionists and increased taxes. It is universally regretted that this wonderful country, which Cecil Rhodes has called "the treasure house of the world," should be so burdened with internal strife, and it can only be hoped that with the coming elections on July 5, a new administration may come in which will give birth to a new era of political quiet and industrial prosperity.

Aluminum

Not many years have passed since, following the discovery of a process by which aluminum can be produced from its ore comparatively cheaply, the columns of the pseudo-technical journals were filled with articles describing aluminum as the metal of the future and predicting that, because of its strength as compared with its weight, it was destined to displace many of the metals now in general industrial use. The claims made by irresponsible people were so extravagant and absurd that the general public soon came to realize that they could never be attained, and consequently discounted every statement made concerning aluminum. As a result the metal, from enjoying high regard, fell almost into disrepute and public interest in it declined. But as a matter of fact, the general features of the statements first made are essentially correct, minor factors having intervened to prevent them from being realized as quickly as expected. Though the cost of the metal was greatly decreased, it was not reduced to a point where the sum total of advantages plus cost was sufficient to cause manufacturers to change their practice, which, in many cases would have necessitated 'scrapping' valuable machinery and abandoning the manufacture of products for which a reputation had been built up through many years of work.

Other factors than mere cost must always be considered. Thus as a conductor for electricity, aluminum at 20 cents per pound is on a par, from the

sandpoint of cost, with copper at 12 to 13 cents. During 1912 aluminum ranged between 18 and 26 cents per pound while copper ranged between 14 and 17½; in other words, sometimes copper was the cheaper and sometimes aluminum, but the latter showed a range of 8 cents against 3½ for the former. The manufacturer and consumer of electrical conductors, therefore, had comparatively little incentive to commit themselves to the use of aluminum, the more so as the supply of the metal was comparatively limited and a few large purchases might send it skyrocketing. This is not all the story, however, for aluminum is comparatively weak in its tensile strength, while the larger cross-section of the equivalent conductor made the wind load and ice and snow load on wires much greater than is the case with copper. To support the wires would require more poles or towers, and what was saved at one pocket was lost out of the other. This difficulty has now been overcome by the use of a composite cable of several aluminum wires about a steel wire, and the transmission line of the Los Angeles power project uses such a cable for its 275 miles of length. There is another difficulty: aluminum, in spite of the early claims made for it, is much more subject to corrosion than is copper, and the same is true of steel. We understand that a means has at last been found of overcoming this drawback, and that henceforth the item of relative cost will practically be the determining one. Assuming that 14 to 15 cents is the normal price for copper, it seems probable that aluminum will henceforth be a keen competitor with it when selling for 20 cents per pound.

It must not be assumed from this that increase in the output of aluminum will be followed by a corresponding decrease in the consumption of copper, for there is almost an infinite variety of uses for aluminum which can absorb much greater stocks of the metal. Its use in the manufacture of cooking utensils, competing with enameled ironware, is known to everyone, and the consumption in this way will certainly increase greatly when the selling price of the finished article is brought closer to the cost of the metal, and the latter is also reduced. In this case its use for the larger-scale cooking utensils employed by the makers of preserved food, liquors, and the various products of chemical engineering is also likely to increase. Another large field is in the manufacture of automobiles, aeroplanes, and other machinery where lightness combined with strength is advantageous. A large increase in the supply, together with a steady moderate selling price is likely to greatly increase consumption in this field. Another field, yet unexploited, is the use of the metal for interiors, supplanting woodwork. In the modern business office almost the only articles still made of wood are the desks and chairs, and it is quite possible that these will soon be supplanted by metal, yielding to the demand for fireproof construction. Painted sheet steel is now the favorite material for all metal construction, but unpainted aluminum would be much more satisfactory from the standpoint of illu-

mination, since it quickly acquires a gray 'mat' surface which diffuses light without creating a glare. The cost of aluminum is now too high to compete with steel in this way, but what the future position of the two will be must be left for the future to show.

Much aluminum is used in ways which are not impressive but which consume a large amount of the metal. Aluminum 'novelties' have become so common that they have lost their novelty, but have proved so convenient that their use is likely to increase rather than decrease. Aluminum foil is now being used, displacing, to some degree, the tinfoil so familiar to our fathers as the containers for 'fine-cut chewin'' and to our sons as the wrapper for expensive cigars. The powdered metal, known as aluminum bronze powder, is used in painting, lithographing, printing, and as a constituent of explosives and a patented source of heat. The early difficulties in working the metal have now been largely overcome, and the manufacture of aluminum tubing, for example, is rapidly increasing. It is not remarkable, therefore, that the consumption in this country increased from 46,000,000 pounds in 1911 to 65,000,000 in 1912, coincidentally with a steady increase in the price from 18 cents in January 1912 to 26 cents in December. It is important to note, however, that even this amount was only $7\frac{1}{2}\%$ of the copper consumption during the same period.

No review of the outlook for aluminum would be complete without some reference to the sources of the supply of the metal. The Aluminum Industry Aktéon Gesellschaft is the largest producer, its plants in Switzerland, Germany, and Austria having a capacity of 32,000,000 pounds per year. This is closely followed by the Aluminum Company of America, with plants at Niagara Falls and Massena, New York. The British Aluminium Company, with two plants in Scotland, is a good third, and there are numerous other plants in France, Germany, Switzerland, Norway, and Italy, which contribute to the total output. The Northern Aluminium Company at Shawenegan Falls, Canada, is the only other plant now producing the metal on the North American continent. However, the Southern Aluminium Company has under construction near Whitney, North Carolina, a plant which will nearly double the present American output when it is in operation. The power supply is to be obtained from Yadkin river, and the technical work is under the direction of French metallurgists. The Aluminum Company of America is also building a new plant at Marysville, Tennessee, and is said to have contracted for 20,000 electrical horsepower from January 1. However, the power company found it necessary to rebuild the dam and these two plants in the south are both likely to begin operations toward the end of the year. Perhaps the most important effect of this will be to give to manufacturers more than one domestic source of supply, and manufacturers who have heretofore been deterred by this fact from committing themselves to the use of a product in which there is now no open market will be encouraged to begin or increase their

use of aluminum. The tremendous increase thus made in the domestic output of aluminum is certain to have a marked effect on the uses and applications of the metal, and it will be interesting to observe whether the increased consumption will take care of the increased yield, or whether a recession in the price will be the result.

Production of Gold in 1913

Since the days of Jason, the quest of the 'Golden Fleece' has absorbed the attention of a large part of the people of all countries. On account of its use and value, gold is the metal of paramount importance in the world, being now the standard of the monetary systems of most of the important nations. From the time of the oldest known civilization, it has been recognized as the most valuable of metals because of its color, lustre, and malleability, as well as its rarity. The Egyptians and Assyrians held gold in high esteem, as is evidenced by the ornaments and jewelry which have been found among the relics in the most ancient tombs, and it seems quite probable that the early Egyptians used gold as a medium of exchange. With regard to its production, there appears to be no statistics earlier than the time of Solomon, although the Egyptian hieroglyphics give the amounts of the tribute paid to the Pharaohs. We are told that the weight of gold which came annually to Solomon was 666 talents, an amount which would be worth today anywhere from thirteen to twenty-six million dollars, according to different authorities. Evidently the gold industry was flourishing as far back as 1000 B.C. and the statisticians were already busy.

Accurate statistics of the world's production of gold are never available, but the annual estimates are close enough for all practical purposes. Exact figures are of no particular use in any event, for the principal value of statistics lies in the indication of general tendencies. Last year we noted that the rate of increase in gold production was steadily declining, and this year we find that the rate of increase has not only been brought to a halt, but that the total output has actually diminished very materially. The table showing the world's production of gold for several years past is of interest, for it shows the great variations in production and the obvious tendency toward a gradual diminution. Our estimate for the year 1913 is based upon official data and accurate figures as far as these are obtainable. The figures for Africa and Australia are official for the first ten or eleven months, December being estimated, and our data for the United States, Canada, and India are based upon estimates furnished by government officers. The Mexican government publishes the figures for the exports of gold for the fiscal year ending June 30, so the estimate of the gold production is based upon incomplete data, although this is fairly accurate.

Official statistics for Russia are seldom published until two or three years have elapsed, but the esti-

mates furnished by our London representative are probably as close as can be secured. It will, therefore, be observed that fully 90 per cent of the world's production of gold can be estimated with a high degree of accuracy, although we deem it foolish to attempt to give anything more than approximate figures. The remaining 10 per cent is contributed by countries from which accurate statistics are rarely, if ever, available. During the year, detailed figures will be published by the governments of Japan, Korea, and the East Indies, but the production of gold from the Central and South American countries is only obtainable by computing the amounts of the importations into other countries during the year. From countries such as China no reliable data can be procured. The production from 'other countries' includes that from Austria, France, Germany, Great Britain, Italy, Servia, China, the East Indies, and many minor producers. The estimates given must be regarded as mere approximations.

WORLD'S GOLD PRODUCTION BY YEARS

| | | | |
|------------|---------------|------------|---------------|
| 1893 | \$157,494,000 | 1908 | \$442,477,000 |
| 1903 | 327,702,000 | 1909 | 454,059,000 |
| 1904 | 347,377,000 | 1910 | 455,260,000 |
| 1905 | 380,288,000 | 1911 | 461,542,000 |
| 1906 | 402,503,000 | 1912 | 475,000,000* |
| 1907 | 412,966,000 | 1913 | 457,928,000† |

*Partly estimated. †Estimated.

The notable increase in gold production during the year 1912 was due principally to the Transvaal. In 1913 the production of the Transvaal declined about \$6,000,000, while that of Rhodesia and West Africa showed slight increases, so that the total output of Africa for the year will be less than that of the preceding year by more than \$4,000,000 worth of gold. This decrease is due in part to strikes and riots in the Transvaal last summer and the great scarcity of labor, and also to the fact that the average value of the Rand ores is diminishing, as is pointed out by Mr. T. A. Rickard and Mr. H. S. Denny elsewhere in this issue. In the United States there has been a steady decline in gold production for some time, and this will probably become increasingly noticeable unless some new goldfield is discovered within the next few years. It is a fact that the richest placers and lodes in the country have already been found and exhausted, with the result that our gold production in the future must come from the large bodies of low-grade ore. The rapidly diminishing production of one mine alone, the Goldfield Consolidated, accounts in a large measure for this decreased gold production of the country, but there have also been important declines in other fields. Alaska, for instance, shows a decrease of about \$1,700,000, which is largely due to the exhaustion of the bonanza gravels of the Fairbanks districts, and to an unusually dry season.

Mexico's condition of unrest and revolution has caused the suspension of mining in many districts in that country, with a corresponding decrease in the gold output, although in the larger camps work has been continued with only slight interruption. The ap-

proaching exhaustion of some of the principal ore-bodies is already having its effect, while the cessation of prospecting on account of the disturbed condition of the country augurs ill for the future gold supply. India is one of the few countries which shows a steady and consistent increase in gold production.

GOLD PRODUCTION OF THE WORLD.

| | 1911. | 1912. | 1913. |
|-----------------------|---------------|---------------|---------------|
| Africa | \$187,738,000 | \$208,795,000 | \$204,343,000 |
| United States | 96,890,000 | 93,451,000 | 88,391,000 |
| Australasia | 59,107,000 | 53,557,000 | 50,680,000 |
| Russia | 32,151,000 | 27,702,000 | 25,000,000 |
| Mexico | 24,880,000 | 24,750,000 | 19,500,000 |
| India | 10,449,000 | 12,088,000 | 12,164,000 |
| South America | 12,340,000 | 11,500,000 | 12,000,000 |
| Canada | 9,762,000 | 12,500,000 | 15,350,000 |
| Japan and Korea.... | 6,890,000 | 7,000,000 | 7,000,000 |
| East Indies | 4,726,000 | 4,980,000 | 5,000,000 |
| Central America | 3,360,000 | 3,600,000 | 3,500,000 |
| Other countries | 13,249,000 | 15,077,000 | 15,000,000 |
| Totals | \$461,542,000 | \$475,000,000 | \$457,928,000 |

During 1914 and the years to come, the production of gold will probably decrease gradually, unless new goldfields of importance are discovered. Improvements in metallurgy will undoubtedly continue to be made, permitting of the working of lower-grade ores, but this science has already advanced so far that future betterments will probably make progress slowly. Much may be expected, however, from the successful mining and milling of the huge bodies of low-grade ore which are known to exist. The operation of the Alaska-Treadwell and the experiments conducted by the Alaska Gastineau and Alaska Juneau companies have proved that ore containing \$1.50 to \$2 per ton in gold can yield a profit where extensive deposits are mined on a huge scale. By the end of this year the last two companies mentioned should be recovering about \$5,000,000 worth of gold annually, and this production will in time be doubled. Increased transportation facilities will greatly aid mining of the lower-grade gold gravels and the vein deposits in the difficultly accessible regions of Alaska. The same is true of Siberia, where vast areas of alluvial deposits lie undeveloped on account of lack of transportation. The consensus of opinion is that the more accessible parts of the world have been so thoroughly prospected that there is now slight probability of discovering goldfields of richness or importance in the regions which are now known. In the future the prospector will be forced to confine his efforts largely to parts of Canada and Alaska, South America, China, and elsewhere, for it is evidently a fact that almost all of the easily mined placer deposits and the outcropping bodies of rich ore have been found, mined, and largely exhausted. The discovery of new fields will depend upon the exploration of distant inaccessible territory, and upon scientific prospecting by means of our vastly increased knowledge of the geology of ore deposits. The mining and treatment of large bodies of low-grade ore will also add greatly to the future production.

Gold and Silver Production of the United States

Estimates for the calendar year of 1913, by the Bureau of the Mint and the United States Geological Survey, with final figures for 1912; printed through the courtesy of George E. Roberts, Director of the Mint.

United States Mineral Output in 1913

Below are given figures of production for 1912, as collected by the United States Geological Survey, and estimates for 1913, for coal and the leading metals, furnished by the courtesy of George Otis Smith, Director, except as noted.

| Coal: | 1912. | 1913. |
|---------------------------|---------------|----------------|
| Bituminous, short tons. | 450,104,982 | 476,000,000* |
| Anthracite, long tons.. | 75,322,855 | 79,800,000* |
| Pig iron, long tons..... | 30,180,969 | 30,500,000‡ |
| Copper, pounds | 1,243,268,720 | 1,223,700,000* |
| Gold, fine ounces..... | 4,520,717 | 4,276,300‡ |
| Silver, fine ounces..... | 63,766,800 | 67,601,111‡ |
| Lead, short tons | 415,395 | 466,843* |
| Spelter, short tons..... | 323,907 | 345,575* |
| Quicksilver, flasks | 25,064 | 23,000* |

*U. S. Geological Survey estimates.

‡U. S. Geological Survey and Bureau of Mint estimates.

‡Iron Age figures for 11 months; December estimated.

*Estimated by C. G. Dennis.

Copper production in the United States in 1913 is estimated by the United States Geological Survey as totaling 1,223,700,000 lb., worth \$187,200,000. These figures may be compared with 1,243,268,720 lb. in 1912, worth \$205,139,338.

Lead production is estimated by the United States Geological Survey as follows:

Total refined lead from domestic and foreign ores, 466,843 tons, value \$41,082,184; the corresponding production for 1912 was 467,342 tons.

Antimonial lead, 1913, 16,338 tons; 1912, 13,552.

Imports (ore, bullion, and refined lead), 1913, 56,717; 1912, 83,560 tons.

Lead content of the ores mined in 1913, 460,512 tons; 1912, 457,355.

Spelter production is estimated by the United States Geological Survey as having amounted to 345,575 tons of primary spelter from foreign and domestic ores in 1913, worth \$39,395,550. The corresponding figures for 1912 were 323,907 tons, \$44,699,166. The recoverable zinc content of ores mined in the United States in 1913 is placed at 414,151 tons.

Canadian Gold and Silver Production

*Canadian gold production in 1913 is estimated by the Mines Branch of the Department of Mines of Canada at \$15,350,000, as compared with \$12,559,443 in 1912. Silver production is similarly estimated at 33,500,000 oz., which may be compared with 31,931,710 in 1912.

What is the Matter With Prospecting?

A SYMPOSIUM

Having in mind the statement often made that mines are not being found as rapidly as is necessary in order to keep up the growing rate of mineral production—in short, that a few years will bring us face-to-face with a metal famine—and the other wide complaint that prospectors can no longer obtain grubstakes for finding and developing new deposits, nor can they sell claims undeveloped, we recently asked a number of prominent engineers and mine owners to aid us in getting at the facts by answering briefly the following questions:

1. *Is it true that money is no longer available in adequate amounts for finding and developing prospects?*
2. *How can additional money be made available?*
3. *Do you believe in government aid to prospecting and prospectors, and, if so, in what way should this aid be given?*
4. *Can prospecting methods or conditions be so improved as to make the available funds adequate?*
5. *How can a better market for undeveloped mineral lands be created?*

The response has been most generous, and from the large number of interesting letters received we have selected a few from which brief abstracts are presented below. We regret that the necessity for condensation makes necessary the omitting of introductory statements and reparagraphing, but we feel sure that our friends and readers will pardon this in view of the significance of the subject-matter. Our own summary and comment will be withheld until more of the letters shall have been presented. **EDITOR.**

Walter H. Aldridge:—There is plenty of money available for investigating new properties which give promise of large tonnages of low-grade commercial ore. There are not many large concerns willing to grubstake prospectors or, in fact, to risk much money in attempting to develop prospects. The developing of the prospect is more the province of the prospector and his associates or small local syndicates. The reason that a large amount of money is not available for prospects is probably due to the fact that the many companies which have had large and varied experiences in exploration work have found the chances of developing good mines from the ordinary prospect are not sufficiently good to justify the many losses incurred in working prospects which do not develop into mines. I do not believe in government aid to prospecting or prospectors, as I doubt whether it would do any good, and there would unquestionably be an immense amount of money wasted if such a plan should be adopted. I do not know how present prospecting methods can be materially improved. The Western prospector will still continue to hunt up good surface showings. If he is successful he will usually interest some of his associates in his claim or claims,

or else get a small local syndicate to back him to a limited extent. If this work is encouraging, the small syndicate usually interests a larger syndicate of greater means. Ample funds can, therefore, be secured so long as the prospect in the first instance is a reasonably good one, and the work subsequently performed gives justification for the first good impressions formed by the prospector. I can not make any suggestions how a better market for undeveloped mineral lands can be created, as the marketability of mineral lands is entirely dependent upon the surface showings, geological conditions, etc., and where these are favorable there is always keen competition to secure them.

Philip Argall:—In reply to your letter of December 5: I find it extremely difficult to interest capitalists in prospects. It is very difficult to find a means. The Denver Chamber of Commerce organized a prospecting company last year, and with all the influence of that commercial body, backed by competent mining engineers and a first-class directorate of leading business men, capital was not available, the company had to be liquidated, and money returned in full to subscribers. Clean business methods were the ideals of the company, and after the great innings of the wild-catters, I now believe the change was too great. Though I regret to say it, visions of high profits are necessary to sell prospecting stock, hence those that "see visions" have their place in mining. I have never known successful issues along the line of government aid. Prospecting combines at once the greatest risks with the greatest profits usually obtained in mining. I am frank to say that it is only the Government clerks in the Forest Service that can at once determine if the budding prospect will develop into a great mine or an expensive hole in the coppice. Those who have spent many years in developing mines are not dissatisfied with one good mine from ten selected prospects. It is a matter of judgment and judgments aided by experience. By forming prospecting syndicates to deal systematically with selected prospects, and by prospectors being more liberal in their terms, giving an interest in the property against development and not demanding payment for the privilege of developing more or less meritorious uncertainties, the market may be broadened.

F. W. Bradley:—Money is just as available in adequate amounts for finding and developing prospects as it ever has been. The prospects may not make as many bonanza mines as formerly, but the development of less wasteful methods and inventive genius will probably keep pace with the world's growing metal requirements. Additional money could be made

available by having the postoffice and other authorities go after the big people in the mining stock swindling game as hard as they go after the small people who sell mining stocks on false representations. No, I do not believe in government aid as a subsidy to the prospectors; but I do believe in the present existing government aid to prospecting, which present aid will probably continue to grow in the same ratio as present government aid to agriculture grows. Available funds are just as adequate for all legitimate mining work as they are adequate for any other kind of legitimate work. A better market for undeveloped mineral lands could be created by stopping the swindling games conducted in the name of mining.

P. R. Bradley:—I think money seeking legitimate mining ventures exceeds the opportunities to risk it where there is a reasonable mining chance for success. Additional funds can be made available by protecting the timid operator against fraud. More publicity should be given to the possibilities in favorable areas. For example, a large English operator recently had trouble in securing data on the output of the Mother Lode area in this state. His idea was that with this data in hand he would have less difficulty in interesting his friends in that territory. I believe in government aid to prospectors only indirectly; that is, by stimulating and assisting the mining industry through the Bureau of Mines so that there will be a broader field of work for the prospector. Improvement in prospecting conditions might be brought about by the assistance of the Bureau of Mines, say by the establishment of district offices, each in the charge of a competent officer whose duty is to study his district with a view to encouraging not only the development of new properties, but also the rehabilitation of old mines where modern practice and new methods may result in their success. A better market can be made by protecting the investor against fraud, and by giving ample publicity to new methods and the demand for minerals not now commonly mined, but which from time to time are sought by new industries.

D. W. Brunton:—It is only too true that prospectors do not now receive the same backing and support from business men that they did ten years ago. In Colorado, this is due principally to the fact that no new mining districts of any importance have been discovered during the past twenty years. Nearly every winter, when the snow is deep and the mountains inaccessible, fairy stories of important discoveries appear in the newspapers, but the next spring, as soon as the districts are accessible, the values vanish. Funds and support can only be obtained by making mining more profitable and by preventing the organization of wild-cat promotions and other fraudulent methods of imposing on the public, through which legitimate enterprises are made to suffer. If, by government aid, you mean the subsidizing of prospecting and mining operations, I would say no, as we have altogether too much paternalism now. The U. S. Geo-

logical Survey and the Bureau of Mines are now doing much more for the industry than any direct grant of funds, and if the appropriations for these two branches could be increased, there is no doubt the industry would be immensely benefited thereby. Improvements in prospecting methods can only be brought about by greater knowledge and skill on the part of the prospectors. Where prospecting has to be carried on in the forest reserves, more common sense and less 'red tape' on the part of the forestry officials would be extremely desirable and decidedly beneficial, not only to the prospectors, but to the forest service as well. An undeveloped prospect is a good deal like a lottery ticket, and, like the latter, will not be a very desirable acquisition unless the prizes are not only large but sufficiently numerous to justify the risk. To this end the complete revision of our present mining laws is extremely desirable, so that, should a man be lucky enough to open a valuable orebody, he would have a reasonable chance of retaining its ownership.

Albert Burch:—I do not believe in government aid to prospectors, but I do believe that the United States should take steps to scientifically prospect and classify its own mineral lands; and, in doing so, should employ the services of both technically trained geologists and mineralogists and practically trained prospectors, on such a basis of compensation as would attract the best men of both classes to the service. I know of a prospecting venture about to be started, in which two men, one of them a good mineralogist and the other a veteran prospector, are to start out as partners, under a grubstake agreement with a capitalist. If young school of mines graduates, with a little mining experience and a fair amount of training in field geology, would seek alliances such as this, instead of positions as assayers, surveyors, and assistants around operating mines, the standard of prospecting efficiency would undoubtedly be raised, and the demand for competent prospectors increased. A young man of this class, with few family responsibilities, could well afford to devote a few years to this kind of work; because, even though not financially successful, the experience would be very valuable to him in his subsequent mining work. Not the least valuable of the lessons which such a life would teach him, would be self-reliance.

George E. Collins:—I have no recent personal experience of raising money for prospects, but from what I hear, I am satisfied that it has become very difficult, excepting from individuals who have exceptional personal confidence in the man who endeavors to raise it. I do not know of any way in which this condition can be changed, excepting as a result of increased public confidence in the business of mining; and this, in my opinion, can only be secured by increased dependence in professional mining engineers, based on a higher standard of principle and honor among them, and enforced by legislation requiring their employment. I do not believe that direct gov-

ernment aid to prospectors is practicable or desirable, excepting as to the dissemination of information. But I believe there might wisely be a system of public money rewards to prospectors who discover mineral deposits of substantial value, but which under existing conditions cannot be profitably worked. I venture to suggest that the federal government, acting through the Bureau of Mines, might purchase such discoveries from prospectors. Prospecting methods will always depend on the individual prospector. Until something is found, and some *prima facie* evidence is secured of the presence of valuable minerals, I fear that organization and technical skill are helpless, and that we must depend for the original discovery of mining prospects on rather haphazard methods. The only way I can see in which to help the prospector is through the technical and semi-technical journals, which can disseminate accurate knowledge about minerals, and the conditions under which they are likely to be found, so as eventually to reach the class from which prospectors are drawn. Speaking generally, the root of the trouble, in my opinion, is a decadence of the adventurous pioneer spirit. Prospectors are fewer than they were, in many other lines besides mining. I do not hear of experienced prospectors of good character being unable to secure grubstakes.

D. Fasken:—I can only speak from experience of the province of Ontario, and reliable prospectors have no difficulty in finding parties ready to grubstake them, but the capitalists are more careful than they were a few years ago as to whom they shall employ. There is a scarcity of men who should go out as prospectors. They have not the technical knowledge. Farmers' sons and all sorts of laborers have gone out without any idea when they are examining rock as to whether they could expect mineral to be found or not. With regard to raising money for developing purposes, I would say that money in Ontario at the present time is scarce, but where a property has merit there are plenty of people prepared to undertake the development. I do not believe in a government aiding prospecting or prospectors. I would not think such a scheme feasible. I think what a government ought to do, and what they are trying to do in Ontario, is to protect a prospector once he has made a discovery, and let him operate as cheaply as possible.

Charles Hayden:—Money is just as available now as it has been in the past, if not more so. It is not the place of a banking house, however, to go into the business of prospecting—that is the business of individuals. I see no necessity for additional money being made available. I do not believe in government aid to prospecting and prospectors, other than the rights and protection which they now have. I do not see in what way prospecting methods can be improved. I do not believe there should be any better market for undeveloped mineral lands created. I

think by good hard work and labor people should develop those privately before asking outsiders to become interested in them.

D. C. Jackling:—In my opinion the apparent lack of interest in prospecting is due more to the lack of fertile fields for such exploratory work than to indifference on the part of anybody to the discovery of new mineral deposits. In other words, the mineral-bearing areas of the United States have been pretty well covered by investigations and developments to varying extent. There is scarcely an area anywhere in the country that has not been investigated by engineers either for the government or through the activities of private individuals or corporations; and, furthermore, the business of mining has taken on in the last few years much more of a scientific character than applied to it in earlier days. In fact, it is becoming a business conducted in a general way, at least, along lines of fairly definite principles, whereas in the days of active prospecting in unexplored areas the general idea of mining investigations and operations partook in some degree at least of the spirit of adventure. I believe there is just as much money available as there ever was for the investigation and development of mineral resources; but, on the other hand, I believe the days of the old time prospector are gone, and with them the time when money can be secured as it used to be for the support of prospecting expeditions. The modern way is to send an engineer to places that are reported through various channels to indicate promise of mineral deposits. Instead of the prospector spending months traveling by wagon or afoot, the engineer goes to a point near his destination by train, and in all probability travels the balance of the distance by automobile, and if the indications justify it, he reports in a definite way, and the result is development on a practical scale; the whole thing requiring weeks or months where it used to require months or years. On the whole, I think, however noble the prospector's vocation, the time is past when it can be either a popular or profitable one; and still I believe that, taking into consideration the possibility of finding new mineralized areas, or new deposits in known mineralized areas, the development and commercialization of the country's resources is going ahead at a more rapid rate today than it ever has at any previous time. There are variations in this activity, of course, depending on industrial conditions, the price of metals, etc.; but considering periods of time long enough to cover such variations from maximum to minimum, I believe what I have said is true, and I think the statistics and history of the mining industry in the United States for the last five to ten years will substantially bear out this view.

Hennen Jennings:—As I have been so little connected with actual mining in this country of late years, I do not care to go on record in attempt to, in detail, answer your questions. I do not think it ad-

visible to invoke any government aid unless it might be in connection with pushing and upholding the report of the committee on general revision of the mining laws of the American Mining Congress. It would seem that our stupid apex law, which was supposed to be so beneficial to the prospector and the poor man, has really been a boomerang and struck back at them, for now people with money are fearful in the initial stage of a mining venture that they may be buying lawsuits rather than ore deposits, and they would prefer paying more money at a later date when the venture had its legal and prospect values better established. The busy and greedy promoter has also overdone things and has had a tendency to frighten honest investors away. At the present time only laws upholding the poor man and discouraging the rich seem in favor with our legislators, and in the end most of them will be found to serve the poor man about as well as the apex and be a detriment rather than a betterment to him.

Benj. B. Lawrence:—The opportunities offered to the prospector in the early days of the development of this country no longer exist. Given new territory, you will have plenty of prospectors. The decrease in the production of the minerals in the state of Colorado, for instance, I believe to be due to the very rapid exhaustion of the mineral deposits heretofore discovered in that state, and the failure to replace the worked-out mines by new ones is simply due to the fact that such mines are no longer easy to find. The citizens of Colorado made an effort through one of the newspapers in Denver to stimulate prospecting and by various measures through the Chamber of Commerce there, but as far as I know, the inducements which were offered to prospectors to 'get busy' have been productive of no results. I believe that there is money available for finding and developing prospects, and that there are men to find them, the difficulty being that the prospects are hard to find. I do not believe in government aid to prospecting or prospectors. I do not think it would accomplish anything, and it would help to develop a very substantial breed of loafers. The prospector was a product of his environment and cannot be reproduced, as existing conditions will not develop the type of man who has been responsible for the discovery of the mineral wealth of this country. That scientific methods of prospecting by expert geologists will ultimately be productive of some good, I do not doubt. In this respect, economic geology has taken great strides, and I am hopeful that as a result of the study of geologists some new mineral deposits will be discovered. Capital will be eager to develop mineral deposits if they really have promise. The trouble is that the undeveloped mineral lands of which we have knowledge are rejections from which have been chosen the properties which are operating and have been operated in the past, and what remains, under existing conditions are not sufficiently attractive to allure capital.

E. J. Longyear:—It is a fact that moneyed men are not as ready to back the prospector as they were in the past. Additional money may be made available by reestablishing public confidence and a reasonable attitude of the government toward mineral development. The government, through its Geological Survey, can be of great assistance to the prospector. I do not favor direct financial aid by the government. There is undoubtedly room for improvement in prospecting methods, but I would not expect such improvement to have much influence in making money more available until other conditions have changed. There is a strong feeling among the people today that no individual or group of individuals should expect to derive from a business venture any more profit than a moderate percentage on his investment. This sentiment is being more or less reflected in recent government actions, and investors hesitate to risk spending money where there is an uncertainty as to whether they are going to be permitted to retain the results of their investments. The inducement that leads the prospector to endure the hardship of the desert, and the capitalist to back him, is the possibility of 'striking it rich.' If they can be assured that their property will not be confiscated, even though the profits may be large, we shall see plenty of money available for developing mineral lands.

John H. Mackenzie:—My judgment is that there is plenty of money still available for developing good prospects, but good prospects are very difficult to find, as there is little territory that has not been 'combed' over in the last ten years. Whenever a new find is made that is really good, there will be plenty of additional money spent in searching for new mines. You remember the boom in prospecting when Tonopah and Goldfield were struck. You also probably know that not over 10% of the money that was poured into Nevada for prospecting and developing purposes went into the ground and that 90% was spent in gambling and riotous living. I do not believe in government aid to the prospector, as I do not think it would be possible to bring the prospector under proper control. As a rule, they are an irresponsible lot. It might be that after a prospector found an outcropping that promised well, government aid could be furnished to develop the prospect; but, on the other hand, if a prospector found a really good looking outcrop, there is plenty of private capital available to help him develop it. I think there is a good market now for undeveloped mineral lands that promise well—the trouble is to find the promising mineral land.

H. C. Perkins:—It is not true that money is no longer available in adequate amounts for finding and developing prospects. I do not believe in government aid except by making titles secure and preventing mining swindles. There are ample funds for clean, honest business. In some localities where dishonest or foolish mining promoters have cost the public heavily, confidence must be reestablished.

M. L. Requa:—It is not true that money is no longer available for developing prospects. Probably at no time in the history of mining has there been a keener competition for meritorious prospects to develop. The great trouble is the lack of satisfactory prospects. I think it is highly probable that there is greater difficulty being experienced now than ever in finding grubstakes, for the reason that experience has proved that it is very difficult in these days for the ordinary prospector to find something sticking out of the ground. I think it has become more and more evident that the mines of the future must largely be developed in territory that shows certain geological conditions, but where ore-shoots are not outcropping upon the surface. The percentage of successes will probably be relatively small. I do not believe in government aid to prospecting or prospectors. If the government is going into the business, it had better do the whole thing—the prospecting and the developing—and reap the rewards. Prospecting methods and conditions do not need improvement. It resolves itself into two great divisions: prospecting in the effort to find something that is sticking out of the ground, and prospecting in the effort to find an orebody that is indicated by certain surface conditions. No great improvement is demanded in prospecting for deposits that show upon the surface; possibly there may be improvements for prospecting for hidden deposits. There is an ample and voracious market awaiting the development of mineral lands that show any value. Boiled down to a few words, the facts are that so far as the United States is concerned, the surface showings have been pretty well found, at least I believe they have. In the future, development work must be done with the hope of finding orebodies that do not crop on the surface. This is expensive and probably will not be a popular form of mining and will be done only by a few concerns. In the meantime, the prospector must seek other fields. I believe that there are still many areas in the world that afford the possibility of finding orebodies showing upon the surface, but I doubt that they exist in any great quantity in the United States.

Arthur Thacher:—There is one point to which I would strongly object, and that is any government aid in prospecting or to prospectors. There are a great many reasons why I think this would be very undesirable. The whole matter, in fact, had best be left to private enterprise. The government can do as it has done in the past; that is, give information and maps, and possibly this branch might be improved or added to, but as for direct aid or undertaking any direct help for prospecting, I think this would be a decided mistake. I know some others might have a different view, but I think the danger in all our government work is that they do not draw the line carefully enough between what is properly government work and what should be left for individual effort. A great deal can be done by the government in general direc-

tions, but when it encroaches on the private enterprises I think it is a decided mistake and will lead to disaster and throw discredit on all the government work.

Benjamin B. Thayer:—I do not agree with what you state seems to be a prevailing opinion, namely, "that mines are not being found as rapidly as is necessary in order to keep up the growing rate of mineral production"; or, "that a few years will bring us face to face with a metal famine." It is my opinion that the old type of prospector is becoming somewhat extinct; I mean by this the individual who went into the mountains alone with his pack-animals, his expenses being generally borne by one or two individuals. In addition to this, the possible prospecting area has become more and more limited, as many sections of the United States have been pretty well run over. The best evidence that prospecting is still going on is in the discoveries in Alaska, where, in my opinion, up to the present time, on account of the inaccessibility of the country and the difficulty of transporting supplies for extensive mining, nearly all of the attention of the prospector has been given to placer mining and not to quartz mining at all points beyond the tidewater districts. I think that as this country is opened up—by this I mean transportation made more feasible—more attention will be paid to the quartz deposits of Alaska, and that doubtless many important mines will be opened up. Again, I think the prospector of today is too prone to place his holdings in the hands of the 'get-rich-quick' promoter instead of relying upon the miner to take the metals out of the ground—a slower but surer process. I do not think it a practicable scheme for the government to attempt to aid the prospectors financially, but I do think the spirit of conservation can be overdone, and the government, by the withdrawal of lands, can seriously hamper the work of the prospector and retard the growth of a district. There is plenty of market at the present time for promising prospects, if, as I have stated before, the prospector will endeavor to reach the capital he needs through the proper channels. It must be borne in mind that the greatest increase in the copper-metal output in this country of late years has been due to the application of new reduction methods to properties whose existence in some instances had been known for over a quarter of a century, and also to the refinement of methods previously in use. To sum the matter up, I would state that in my judgment there is no dearth of market for the wares of the prospector, and many mining men of authority still believe that "it is cheaper and safer to buy your eggs and hatch them, than it is to buy full-grown hens."

Accidents in metal mines of the United States, according to the Bureau of Mines, in 1912 resulted in the death of 661 men. In addition 4502 were seriously and 26,232 slightly injured out of 169,199 employed.

The International Engineering Congress

By H. FOSTER BAIN

Among the important events now being planned for next year, the Engineering Congress which is to assemble in San Francisco, September 20, 1915, easily takes front rank. Held under the patronage of the five national societies, the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers, and the Society of Naval Architects and Marine Engineers, and with a total guarantee fund of \$37,500, the Congress is already assured of success. Membership is open to anyone upon payment of a small fee, and it is hoped that the total enrollment will at least approximate 10,000. More than 70 engineering societies in America and abroad have signified their acceptance of the invitation to take part. While anyone may belong and may obtain such volumes of the proceedings as he may care to pay for, participation in the program will be by invitation only.

The Congress is under the management of a board consisting of 28 representatives of the five societies named. The president and secretary of each society is *ex officio* among the number, and the ten so selected constitute the 'Committee on Participation' which has its headquarters in New York. It is through this committee that all invitations to take part in the Congress are issued, and it is to this committee that Colonel George W. Goethals has signified his acceptance of the presidency. Active direction of affairs is in the hands of a Board of Management composed of 18 representatives of the five societies, resident in San Francisco, and of which W. F. Durand, of Stanford University, a delegate from the Society of Mechanical Engineers, is chairman, and W. A. Cattell, of the Society of Civil Engineers, is secretary. The representatives of the Institute of Mining Engineers are Edward H. Benjamin, Newton Cleaveland, W. S. Noyes, and H. Foster Bain. The board holds monthly meetings and acts through an executive committee and sub-committees on finance, papers, publicity, and local affairs. The latter will have charge of quarters, transportation, entertainments, and excursions. Mr. Benjamin, its chairman, is at the same time a member of the executive committee.

The papers committee has been busy outlining a program and tentatively making up lists of names as a basis for invitations to prepare the papers and discussions of the Congress. It is planned to publish the latter in 10 full volumes and one half-volume, the latter to include the proceedings of the opening session and those papers that deal especially with the Panama canal. Space in the other volumes is to be allotted so as to permit covering the widest possible range in engineering. It is proposed that they shall collectively constitute a virtual encyclopedia of present-day practice, so far as main outlines are concerned.

It is desired that the papers shall be of the 'Recent Progress and Present Status' type, and that instead of dealing in a restrictive way with particular problems or describing particular constructions, they shall summarize important lines of progress in each branch during the last decade and note the present practice and probable future trend.

Metallurgical Papers

To mining and metallurgy a total of 750 pages has been allotted, though many closely related subjects will be discussed in the volumes devoted to civil, electrical, and mechanical engineering. With the active coöperation especially of T. T. Read, Bradley Stoughton, and C. W. Merrill, the following general outline for the metallurgical volume has been prepared. It is proposed that the volume shall constitute what may be termed a cross-section through the metallurgical industry in 1915. The larger topics will each be under the general supervision of a special editor who will have charge of collating and arranging the papers by individual authors. It is not intended to exclude the citation of special instances to illustrate the general treatment of a subject, but such citations should preferably consist of references to the bibliography of the subject which will serve to supply the reader with measurably full indication of the sources where important original papers may be found. In particular, it may be noted that within the extent of space available, it is not expected that the treatment can be to any marked degree detailed in character. It is desired rather that it shall be broad, comprehensive, and suggestive. The general subject will be considered under 11 heads with sub-topics indicated:

1. Iron and steel—Metallurgy of cast steel, including founding; manufacture of steel and wrought iron; properties, uses, and manufacture of alloy steels; metallography of iron and steel; corrosion of iron and steel.

2. Copper—Copper smelting practice; hydrometallurgy of copper; copper refining; copper alloys; physical properties and metallography of copper.

3. Cyanide practice—Preliminary crushing; re-grinding; solution of gold; filtration; precipitation.

4. Metallurgy of zinc and cadmium.

5. Lead smelting and refining.

6. Metallurgy of aluminum.

7. Minor metals—Nickel and cobalt, mercury, tin, arsenic, antimony, and others.

8. Metallography and technology of non-ferrous alloys.

9. Electrometallurgy—Iron and steel; aluminum; zinc; copper.

10. Utilization of fuels—Pulverized coal; liquid; gaseous.

11. Ore dressing—Crushing and sorting; wet-con-

centration; magnetic work; flotation.

The volume on mining engineering has been planned with the special assistance of H. C. Hoover, F. W. Bradley, M. L. Requa, D. C. Jackling, and incidental help from other members of the Institute. In it a slightly different point of view has been adopted. It has been thought that the most serviceable volume that could be produced would be one in which should be summarized the best engineering practice as relates to distinctively mining problems. With this in view, it has been proposed to leave to the other sections of the Congress the handling of subjects that are only incidentally mining and to bring together a group of papers that would afford a concrete picture of mining methods in 1915. It is thought that best results will be obtained by collections of somewhat detailed descriptions and analyses of the different mining methods as exemplified by type examples and supplementing these by very brief bibliographies and carefully planned discussion rather than by a general résumé of the literature of each topic. The purpose is, as far as may be, to have each subject handled by a practicing engineer who has himself employed the method described. The following list of papers is proposed:

Papers on Mining Methods

1. Placer mining, including: (a) the testing and valuing of placer ground; (b) hydraulicking (briefly); (c) dredging, the latter to be discussed in detail and to form the main part of the paper. In this and subsequent papers named, the object should be to describe the methods, efficiency, and limitations of the process. The recent use of dredges for stripping iron ores may well be taken up in the discussion of the main paper.

2. Steam-shovel mining: (a) the methods on flat lands with heavy cover, as in the Lake Superior iron district; (b) modified methods on steep slopes, as in the Western copper mines, with consideration of the methods of preparing and blasting the ground; (c) substitution of drag-line scrapers, as in the Cuban iron-ore mines; (d) mill-hole work.

3. Caving systems in mining: (a) methods as employed in the Lake Superior iron mines; (b) modified methods used in Western copper mines.

4. Method used at the De Beers diamond mine. This was developed from a coal-mining method in wide use and shows relations both to caving and narrow stoping.

5. Stopping as used in the Lake Superior copper mines with great depths and low angles of dip.

6. Mining methods on the Rand, as an example of stoping at great depth in persistent orebodies and where large-scale operations are possible.

7. The cross-stopping method in use at Broken Hill, New South Wales.

8. The rill and fill system at Kalgoorlie.

9. Methods of filling. These methods have been worked out especially in European coal mines and are beginning to be employed at Seranton, Cripple Creek,

and other points in the United States. They must ultimately be used even more widely, and the topic is therefore especially important.

10. Underground transportation. These methods have been developed most largely in coal mines, and the metal miners have much to learn in this particular. Grades, curves, track, motive power, cars, signals, and dispatching are some of the subdivisions to be considered.

11. Hoisting from depths, with Butte as the type example. Butte is chosen because of the fact that the engineers there have passed through the stage of direct steam, and in the district may be seen both electric hoisting and a peculiar method of using compressed air; a comparison and a study of limitations of these systems would be especially important.

12. Preparatory work and experimental mining and milling. Now that mines are worked upon such a scale that millions must be invested in preliminary work and in plant equipment, it becomes important to know what are the most economical methods and what the wise limits of expenditure. Test-pitting, drilling, underground exploration, sampling, estimating, testing, the building and operation of pilot-plants, should all receive attention. The ratio of preliminary expenditure to total investment is one to be carefully studied.

13. Underground costs and efficiencies. This should be a general paper treating the subject in a broad way, not a mere compilation of unrelated costs. So far as possible figures should be reduced to a basis of tons per man per shift, and the relative economy of different types of labor and of labor as against machines, studied in detail.

14. Oil production, with especial emphasis on oil-well drilling. This involves engineering of a high degree of skill where many conditions must always remain unknown. Oil is now an important part of the mineral output, significant from many points of view.

Supplementary Meetings

In addition to the Engineering Congress proper, several similar meetings will be held about the same time. The Electrical Engineers plan a separate world's congress for the week preceding the Engineering Congress, and about the same time the American Association for the Advancement of Science, and its affiliated societies, will be meeting. In the week following the meeting of the engineers, an International Petroleum Congress is to be held, and at some convenient date the American Institute of Mining Engineers and the Mining and Metallurgical Society are also to meet. Following the meeting of the Sixth International Congress of Mining, Metallurgy, Applied Mechanics, and Practical Geology, which is to assemble in London in June under the auspices of the Institution of Mining and Metallurgy, an excursion through Canada is planned under the patronage of the Canadian Mining Institute with a visit to San Francisco and a return through the United States to be arranged by the engineers of the latter country.

The National Radium Institute

By ARCHIBALD DOUGLAS

Through the investigations of the U. S. Bureau of Mines, it became evident in the latter months of 1912 that valuable radium ores were being shipped abroad to be manufactured into radium which was being sold back to this country at prices entirely incommensurate with those paid for the ores themselves. But worse than this, it was discovered that at least twice as much uranium oxide and its accompanying radium was being wasted in the low-grade ores that were thrown on the dump and the fine carnotite dust was being swept away by the winds and rain. Knowing the excellent work being accomplished by the Austrian Radium Institute and the Radium Institute of London, Charles L. Parsons, chief of the division of mineral technology, of the Bureau of Mines, proposed to Dr. Howard A. Kelly of Baltimore and Dr. James Douglas of New York—both of whom he knew to be deeply interested in securing radium for use in two hospitals with which they were closely connected—that they form a Radium Institute and endeavor to work up some of our American ores and keep the radium in this country for use among such of our own people as could be reached by such quantities as were secured.

It was agreed, if the ores could be procured, that the Radium Institute would be founded and necessary funds furnished to work up the raw material. Mr. Parsons went with Dr. Kelly to the Paradox valley in Colorado and inspected the mines there. On their return a conference was held with the officers of the Crucible Steel Mining & Milling Co. who owned 27 claims in Montrose county, Colorado, which it had been holding pending such time as it would pay to extract the vanadium and uranium therefrom. The officers of the Crucible Steel Mining & Milling Co., appreciating the immense good that the radium in these ores might accomplish, consented to have these claims worked on a royalty basis under an agreement covering the return of the uranium and vanadium content of the ore to them. Further conferences were then held with Doctors Kelly and Douglas, and the National Radium Institute was incorporated as announced in the paper given by Mr. Parsons before the American Mining Congress, at Philadelphia, October 24.

For some months the Denver office of the Bureau of Mines had been carrying on laboratory experiments and investigations in the field with reference to the uranium ores, and a bulletin covering these investigations has just been published by the Bureau. Knowing of the work of the Bureau of Mines, the National Radium Institute proposed a coöperative agreement with the Bureau of Mines whereby the Bureau was offered an opportunity for scientific and technologic study of the mining and concentration of the carnotite ores in the claims secured by the National Radium Institute; and for studying in the plant of the Institute the most efficient methods of obtaining radium, vanadium, and

uranium therefrom, with a view to increased efficiency of production and the prevention of waste. The legality of the agreement was carefully looked into and full approval given by the government officials, it being found that there were many precedents in similar coöperative work, especially between the Department of Agriculture and the farmers of the country.

In the agreement with the Bureau of Mines, the technologic management of the mines and mills was to be guided by the scientific staff of the Bureau, and Mr. Parsons has been designated by the Director to have charge of the investigation. He will be assisted by R. B. Moore, physical chemist in charge of the Denver laboratory who will have direct management of the plant, and by Karl L. Kithil, mineral technologist of the Bureau who will be in charge of the mining and concentration. Plans have been completed and contracts let for the experimental plant to be erected at Denver; land for the plant has been leased; over 100 tons of carnotite has already been obtained; and the larger part of the apparatus has been ordered.

In connection with the production of radium, the separation of uranium and vanadium will also be studied, and all processes, details of apparatus and plant, and general information gained will be published for the benefit of the people. As a result of these experiments it is hoped that other plants will be erected and that our carnotite ores will be worked up at home and the radium kept in this country. The Institute was formed for the special purpose of procuring enough radium to conduct extensive experiments in radium therapy, with special reference to the curing of cancer. It is also expected to investigate the physical characteristics and chemical effects of radium rays.

The radium produced will not be for distribution, as the work of Dr. Kelly has distinctly shown that to get real results in the treatment of cancer and other malignant diseases a high concentration of gamma rays is essential, and this at the present time can only be obtained from a comparatively large amount of material. Accordingly, to distribute the radium among many hospitals or physicians would render it practically ineffective for this purpose. Some hospitals at both New York and Baltimore are already partly supplied, and while it will be some time before a sufficient quantity of radium is produced from these ores to add greatly to the present usefulness of these hospitals, it is sincerely hoped that the work of the Institute will be of real benefit to many by assisting or possibly in controlling cancer, the most malignant of diseases.

Besides being of benefit to the general public, the activities of the Institute are sure to assist the prospector and miner by providing a greater demand for his already rare ore and by assisting to conserve the large waste which is now taking place; also to the plant operator by developing methods and by creating a larger market for his products. The radium produced is intended for the Institute's own use and is not for sale or distribution.

Work of the National Societies

American Institute of Mining Engineers

By CHARLES F. RAND

The American Institute of Mining Engineers, the second of the four largest national engineering societies, was founded on May 16, 1871. Its membership has grown during its 42 years of life until, at the present time (November 1, 1913), there are 4509 members on the rolls. This is the largest in its history. The growth is shown in the following figures:

| | |
|------------|------|
| 1871 | 284 |
| 1881 | 1035 |
| 1891 | 2082 |
| 1901 | 2799 |
| 1911 | 4210 |
| 1913 | 4509 |

Of the 4509 members, 3228 reside in the United States, 181 in Canada, 254 in Mexico, and 846 in other countries, including almost every corner of the globe.

Founded in a time when the profession of mining engineering practically included that of metallurgy, the name American Institute of Mining Engineers was sufficiently comprehensive to describe its scope, even though its activities have been concerned more with metallurgy than they have with mining and geology. A recent attempt to change the name to American Institute of Mining and Metallurgy, was dropped because of sentiment as well as the pressure of other matters which were at the time deemed to be of greater importance.

It is the will of the members that Institute membership shall be democratic in character, and any person who is actively engaged in mining, metallurgy, geology, or chemistry is eligible to full membership, regardless of technical education or length of experience. Associate members are those persons who are interested in the activities of the Institute; junior members are students in good standing in undergraduate courses of engineering schools. While following the will of the members in admitting all eligible persons upon a democratic basis, the present Committee on Membership gives the strictest scrutiny to all applications, and demands convincing evidence of applicants' standing and eligibility before recommending them for election.

Publications

The chief activities of the Institute are devoted to the distribution of information on mining, metallurgy, and geology by the presentation and discussion of technical papers at general meetings of the Institute and at meetings of the local sections, and by the publication of the best of these papers in the monthly *Bulletin* and annual volume of *Transactions*. The volume of publication has grown so large that, notwithstanding the rejection of a large percentage of papers received in 1913, the first

ten monthly *Bulletins* of that year contained 2604 pages, and, for the first time in the history of the Institute, it will be necessary to issue three volumes of *Transactions* to contain all of the valuable papers and discussions that have been accepted and presented at meetings. The money paid for printing and distributing the publications of 1913, not including editorial expense, was equal to the total amount received from members in dues. The several thousand dollars required for editorial and office expense, contributions for local sections, technical committees, etc., had to be secured from other sources of income. It is thus evident that in the *Bulletin* and *Transactions* alone the members receive more than the full value of their annual dues. In 1913 the Institute also published the Emmons volume on 'Ore Deposits,' which is a continuation of the previous Posepny volume.

The first local section of the Institute was established, after two preliminary meetings for the reading of papers, in May, 1911, with headquarters at New York City. Since that time, nine local sections have been established, in several cities, and steps are being taken for the organization of others in this, and in one foreign, country. The purpose of these local sections is to extend the benefit of the Institute by more frequent meetings of the members in each locality, for reading and discussion of papers, and for social intercourse and acquaintance.

Technical Committees

Because of the wide diversity of subjects included in the Institute's field of activity, and the necessity of specializing in order adequately to take care of these several interests, the Board of Directors has established a number of technical committees, which shall have charge of the interests of the Institute in their respective fields. Although the desirability of such action was suggested by William B. Potter in his Presidential address to the Institute in 1889, in the following words: "It is hardly to be expected, perhaps, in an organization grown to such proportions as the Institute has assumed in the number of members and variety of interests represented, that a very efficient discharge of all its duties could be accomplished without the assistance of the systematic methods which a more definite organization would supply. In the scientific associations of wide and general range, the several interests are usually classified into groups and sections more or less fully organized and equipped for independent work; and it has already been suggested that it might be well for the Institute to adopt a similar course. As a suggestion for such a grouping at the start, the following might serve: I. Iron and Steel; II. The Precious and Base Metals; III. Geology and Mining; IV. Chemistry;" the first such committee—the Iron and Steel Committee—was not established until April, 1912. This committee was successful in securing for the Institute a large number of important

papers and discussions on the subject of iron and steel, and its activities have been so important that in October, 1913, it conducted a general meeting of the Institute under its own auspices, for the presentation and discussion of papers. The second committee to be formed was that on Precious and Base Metals. This committee secured for the Institute a series of papers of very great value, which were presented and discussed at the Montana meeting of the Institute and will be published in Volume XLVI of the *Transactions*, to be known as the Montana Volume. There are now eight Technical Committees in all: The Iron and Steel Committee, chairman, Albert Sauveur; Precious and Base Metals, chairman, Charles W. Goodale; Mining Geology, chairman, James F. Kemp; Mining Methods, chairman, David W. Brunton; Use of Electricity in Mines, chairman, William Kelly; Mining Law, chairman, Horace V. Winchell; Petroleum and Gas, chairman, Anthony F. Lucas; Non-Metallic Minerals, chairman, Heinrich Ries.

The Institute can best carry on its work when all desirable, eligible men are on its membership rolls, and one of the functions of these technical committees is to secure the membership of desirable men within their fields of activity. More than one hundred members were added during its first year by the Iron and Steel Committee.

The formation of the technical committee has been one means of bringing to the attention of the Institute management the large number of men who should be interested in the Institute's activities, but who are not members. For the purpose of securing the coöperation of all such desirable, eligible persons, a Committee on Increase of Membership was formed and through their efforts a number of new members have been secured.

Library and Office Activities

Upon moving into the United Engineering Society's Building in the year 1906, the Institute's library was merged with those of the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, and placed under joint management. This combined library contains now over 55,000 volumes and regularly receives about 700 technical periodicals. The members have been slow to learn of the services which the library can perform to those who are not able to visit it; namely, by furnishing lists of references, abstracts, translations, copies, by lending books through the mail, etc.; but, notwithstanding this, the library is rapidly increasing its activities for members residing at a distance.

Mainly through the efforts of Dr. James Douglas, the land debt of the Institute, which was originally \$180,000, will be entirely paid off at the time of the annual meeting on February 17, 1914. This wiping out of the debt will not only relieve the Institute funds of the payment of interest, but will give the Institute an unencumbered ownership of one-third of the United Engineering Societies Building, and the land on which it stands, worth altogether about \$1,750,000.

The Institute has recently established an Employment

Department with the object of bringing employer and employee together. Although the work of this department has naturally been handicapped at first by lack of knowledge on the part of the members of the services which it can perform, it has been able to fill a number of positions during the past three months and its activities are rapidly increasing. The Employment Department not only publishes a list in the bulletin of 'Positions Vacant' and the 'Engineers Available,' but is in frequent communication by mail and wire with those whom it can serve. As soon as the members of the Institute who are employers of engineers realize that the Employment Department is in a position to secure for them very promptly efficient men well suited to their requirements, this department can expect a great increase in its activities. The Institute maintains in New York a Members' Writing Room.

The policy which the directors have favored this year has been that of encouraging participation in Institute affairs, through the committees, of as large a number of influential men as convenient. The result should be that the management will become impersonal and the Institute's welfare at no time be dependent on any one man.

The Mining and Metallurgical Society

By H. M. CHANCE

The Mining and Metallurgical Society of America is just completing the sixth year of its existence, a year in which its activities have broadened and its functions have expanded. I believe that the consensus of opinion among its members is that the year has brought about a better understanding of the aims and objects of the Society, fuller appreciation of its value to its members and to the profession at large, and a truer understanding of its position as an association which requires and maintains a certain standard of attainments—in experience, professional standing, achievements, or knowledge—as a qualification for membership, but which is in practice an essentially democratic body.

Its members have understood from the outset that the Society was organized to perform functions heretofore neglected or but partly performed, and to provide a representative body by or through which the profession might speak on matters of professional or public interest, but whether it should also undertake work in other directions was not fully determined, and for this reason it has been moving slowly and deliberately, learning by experience, but at the same time it has been working steadily and successfully to carry out the objects of its organization. Its success in this direction has largely been through the efficient and painstaking work of its committees. The steadfast loyalty and unity of purpose shown by its members during the past year have strengthened and rapidly matured the Society, conferring upon it, while still young, individuality and character in keeping with its tenets.

In addition to the publication of matters relating to

its current business affairs, the *Bulletin* of the Society has included matters brought before the Society for action, a number of technical papers, contributions, and communications upon geological and mining subjects, the discussion of some sociological problems and reports from its committees on Mining Law, Standardization, and on Rules for the Award of the Gold Medal of the Society. During the year the Society has passed resolutions memorializing the Congress of the United States to pass legislation providing for: (1) a new building for the United States Bureau of Mines; (2) a new building for the United States Geological Survey; and (3) the creation of a Patent Commission to recommend to the congress of the United States any legislation that may be deemed necessary or expedient. As already announced in the *Bulletin* for November, the gold medal of the Society has been awarded to Herbert C. Hoover and Lou Henry Hoover for distinguished contributions to the literature of mining. The medal will be presented on January 13, 1914, at an evening session of the Annual Meeting of the Society which is to be held in New York City on that date. The Society will close the year in prosperous condition. It has an income larger than its expenditures, no debts, and a satisfactory surplus in its treasury.

As the Society is too young to have a past by which its future activities may be forecast, the interest of its members is centred upon its present and future, upon what it is doing and can do for its members, and upon what it is doing and may do for the profession at large. I shall not attempt to discuss the many useful functions of the Society, but will mention only those that, in my opinion, are of dominating importance.

Many of our members believe that the greatest service the Society can perform for its members is the promotion of engineering fellowship and friendship by drawing together in close association those who are interested in like work and who are actuated by like motives, and I think this belief is well founded because such association enables them to coöperate (within the Society) in advancing the interests of the profession. For precisely similar reasons it seems to me that the greatest service the Society can render the profession at large is to assist in bringing about a more thorough realization of the community of professional interests—in promoting professional solidarity—a matter of profound importance to the profession. Within the Society, professional solidarity has made rapid progress. It is the force that now directs the activities of the Society and is one that must always be an important factor in controlling its destiny. How the influence of a like force can be extended to the profession at large may well occupy the future attention of the Society and of other kindred engineering organizations. These are some of the larger issues with which the Society will be expected to deal. They open fields of work in which the activities of the Society may expand indefinitely.

Perhaps this résumé would not be complete without some reference to the work of the local sections. Those members of the Society who are able to attend the

local section meetings, find pleasure and profit in the discussions of technical matters, especially in the free expression of personal views and recital of personal experiences which the informal character of these meetings permits. To enable a larger number of its members to enjoy these privileges, one of the future objects of the Society will be to establish local sections at a number of places convenient to the location of its members.

The American Mining Congress

By CARL SCHOLZ

The aim of the American Mining Congress has been, and will continue to be, the furtherance of any movement which will be of benefit to the mining industry, with special reference to the wishes of the greater number. The correct solution of the problems which will be of help to the majority with the least injury to the remainder is a task requiring due consideration and support from all quarters.

Perhaps the most important work rendered by the Mining Congress has been its work in assisting in obtaining, first, the establishment and, later, the necessary appropriations for the maintenance of the United States Bureau of Mines. There can be no division of opinion that the first duty of mine owners is to safeguard the lives of the employees. That the Bureau of Mines has more than justified its existence does not require any further affirmation, but we believe its power and influence should be extended, and there is additional work for the American Mining Congress in this cause.

Aside from matters of safety and economy in operating, general economic conditions are becoming more important to mines in this era of expansion when the growth of the industry increases by leaps and bounds; and decided changes in business methods become not only advisable but imperative. Within a half century the early mine operator who aided in the mining of his product was his own superintendent, engineer, and salesman, has developed into the head of operations whose daily output is many times greater than his former annual tonnage. Like changes have taken place in the methods of buyers, and laws have come to life regulating or endeavoring to regulate the industry. The old state of interests of the community is giving away to community of interests, and with the great number of vexing problems, no single individual or even a state organization can satisfactorily maintain its position.

The purpose of the American Mining Congress is to bring together the mine owners scattered throughout this vast country, and by concerted action endeavor to improve the conditions of the industry in a dignified and broad minded manner; to this end the coöperation of all mining men is invited, and it is believed that their moral and financial aid will be amply justified by results which can only be accomplished by united action.

The London Market

By T. A. RICKARD

Introductory.—The year 1913 has been so full of trouble to the mining market in London that those who are superstitious may be forgiven for referring to the second half of its name. It began under a cloud of anxiety created by the first Balkan war, and before the early summer had seen that settled, the complications over Scutari threatened an embroilment of the Great Powers. Then just when the spectre of a vast conflict was vanishing in the Near East, the bourses of Europe were agitated by the internecine strife between the Balkan allies, the conclusion of which brought further burdens in the shape of an insistent demand for loans on the part of the exhausted combatants.

Meanwhile, the trouble in Mexico had been simmering, with occasional explosive outbursts of anarchy, as when the Madero government went down, early in the year, and Huerta advanced through assassination and riot to the presidential chair. During the summer the hope was insistent among those interested in Mexico that the latest military adventurer to rise to supreme power would prove an effective despot, and that order would be brought out of chaos, so that mines and railways could be operated without molestation. But the unruly element masquerading under a new name continued to devastate the country, and caused the cessation of industry over large areas. In the closing months of the year the diplomatic intervention of the United States has threatened, from day to day, to find a sequel in an armed incursion that could only end in a big and costly war. These events, of course, have had a dire effect. Mines have closed-down, many have been looted, others are crippled by the breakdown of railway transport. The railways have been dynamited or used for military purposes until the conduits of commerce throughout Mexico have been put out of use. As many of them have been financed in London, the present loss and the probability of greater damage to investors have contributed to the general dismay.

Besides these events, the mining industry of South Africa has received a body blow from the effects of which it is still staggering. A strike of white miners at the end of June led early in July to a sanguinary riot in the streets of Johannesburg. The cessation of work at many mines was bad enough, but the intimidation of the natives by the wild acts of their bosses was worse, for it led to an exodus of black labor from the Rand.

Thus war, insurrection, and riot have loomed large during the year, freezing the currents of speculation, and causing a shrinkage of quotations that, as we shall see, is astounding. Indeed, the absence of defaults and bankruptcies, entailing a panic, is a striking feature of the position, even if it brings but a lugubrious satis-

faction. The organization of modern business was never exemplified to better advantage than in the ability of the financial interests to withstand a strain so long, so severe, and so aggravating. The fact that the strain has been withstood warrants the expectation that it will be overcome finally. But so long as war between the United States and Mexico looms in the foreground, it is not likely that any market recovery will be recorded.

Among the shocks to public confidence, such as are due partly to the risk implicit in mining and the frailty inherent in joint-stock finance, are the disappointments or fiascos associated with the Orsk, Eldorado, Esperanza, Santa Gertrudis, Mount Elliott, Bwana M'Kubwa, and Great Cobar mining companies. On the other hand, gratifying developments highly encouraging to shareholders have been recorded during the year in connection with the Mount Morgan, Golden Horse-Shoe, Oroville Dredging, Nundydroog, Kyshtim, Tomboy, Naraguta, Renong, and Burma mines. Owing to the general shrinkage of quotations, the improved prospects of many other mines have not been reflected in market valuations, but the number of them is considerable.

Transvaal.—The output of gold, on account of labor troubles, will scarcely exceed that of 1912, which was £38,757,560 or \$188,749,317. The mining industry of the Rand has passed its zenith, as is indicated by the diminution in dividends, compared with the gross output and so-called 'profits,' the last being a purely fictitious statistical statement of a highly misleading character.

| | Gross. | Profit. | Dividends. |
|------------|-------------|-------------|------------|
| 1910 | £30,703,912 | £11,567,099 | £8,887,185 |
| 1911 | 33,543,479 | 11,415,861 | 7,763,086 |
| 1912 | 37,182,795 | 12,678,095 | 7,952,994 |
| 1913 | 37,000,000 | 11,350,000 | 6,500,000 |

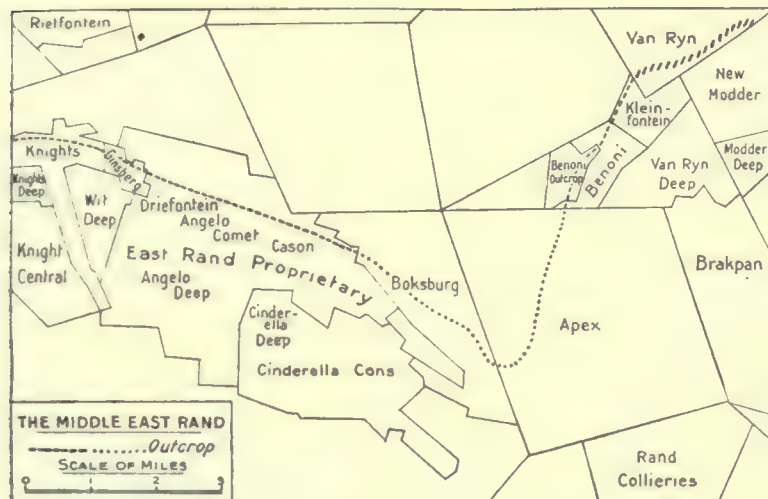

These figures, be it noted, apply to the Witwatersrand district only and do not include the 'outside' districts of the Transvaal. The totals for 1913 are, of course, estimated.

Reference has already been made to the strike and riots in July. These have exposed the fact that the normal complement of 25,000 white men does not consist of manual laborers, but of overseers in charge of the 200,000 Kaffirs. The native is bossed by the white man, who receives from \$135 per month at surface to \$375 per month on contract underground. Against this the colored worker is paid 50c. per shift, and is housed and fed in a compound. He costs the companies about \$20 per month. Owing to incitement by labor agitators from Australia and America, the white worker has become increasingly assertive. For this he has some excuse, but not much reason. The excuse is the prevalence of phthisis, which itself is largely due

to the workman's unwillingness to adopt palliatives, such as respirators and water-sprays. On the part of the companies, the deficiencies in ventilation may be cited, and the lack of effective control, due to the centralization of management at the head-offices of the financial groups, whereby the manager has lost prestige and influence with his white employees.

Engineering & Mining Journal in May, 1903, in which I deprecated the suggestion that the blanket lodes of the Rand had the uniformity and persistence of coal seams. The conglomerate persists, but the gold decreases, in depth. When a blanket ceases to be profitably gold-bearing it loses its economic characteristic and becomes the plain 'pudding-stone' of early Victorian geology.

Last year at this time I was able to instance the development of the Far Eastern portion of the Rand as an outstanding feature of the year. During 1913 the progress of work has been highly satisfactory in the case of the Van Ryn, the New Modderfontein, the Modderfontein B, and the Modderfontein Deep, but results from the Brakpan, Government Mining Areas, and Geduld have been disappointing. The Brakpan has had a bad time owing to a caving of the hanging wall and the poor returns from new workings. The drop in the quotation has been lamentable. The following list of quotations exhibits the fall in market appraisals of the leading mining companies operating on the Rand:

Dissatisfaction, some of it real and some of it merely vicious, has thrown the local industry out of gear, and on the top of that the violent quarrel among his bosses of the dominant race has caused the Kaffir to become unruly in some cases and intimidated in others. Hence the unwillingness to renew contracts on the part of time-expired natives. The recruiting for colored labor had been vigorous and far-reaching; finally, in March, the total supply was augmented to 231,700, but even that did not suffice for the needs of the mines. Then came the strike and the cessation of recruiting, with rapid withdrawals to the kraals, until in October the total supply had shrunk to 170,000, the lowest since the early part of 1910.

This shrinkage has been hardest on the low-grade mines, which, to earn a profit, must be operated on the full scale. As the low-grade mines are also, for the most part, the deep-level properties, it is not surprising that several of them are defunct. Among the mines that have closed down are the Apex, Benoni, Cloverfield, Cinderella Consolidated, Jupiter, French Rand, Van Dyk, Simmer & Jack East, Rand Klip, Lancaster West, Rand Collieries, Volgelstruis, Treasury, and Jumpers. The last two are outcrop mines with a good record, but now exhausted. Among the mines on which operations have been discontinued are two of the deepest on the Rand. This may be noted in connection with the statement of H. H. Webb, in his report for the Consolidated Gold Fields of South Africa, that the mines of that group show undoubted signs of impoverishment in depth. In this respect the Gold Fields properties are not unique. The recognition of this basic fact of non-persistence of ore is interesting, but belated. Some of my readers will remember an article entitled 'Even Methuselah Died,' written by me in the

| | Dec. 1, 1912. | Dec. 1, 1913. |
|-----------------------------|---------------|---------------|
| Rand Mines | £61½ | £5½ |
| Central Mining | 9¾ | 7½ |
| Con. Gold Fields | 3¾ | 2 |

| Van Ryn | 3¾ | 3¼ |

As I said last year, the space given in this review to the Transvaal emphasizes the dominance of the Kaffir market, as is called that department of the Stock Exchange devoted to Rand securities. The gloom at Johannesburg is bound to affect the whole mining market. Liquidation has been on a big scale, as quotations show, but it has not, I believe, gone too far, in most cases. The market valuation of mines is preposterous in boom times, it is exaggerated in ordinary times, and it only comes down to realities in periods of excessive depression. A rebound may be expected, but it is likely only to afford the insiders a chance to unload on the public.

Rhodesia.—The annual output of gold, estimated at £2,900,000, shows an increase; but it is small, and in no proportion to the discounting of the future that has marked Rhodesian finance. I confess to a prejudice against this part of Africa, for it has been the scene of the most unblushing stock-jobbery, highly injurious to the business of mining. During the year the notorious Amalgamated Properties has gone to the wall, with reconstruction; the Giant has gone 'scat,' as the Cornish-

man says; the Eldorado and Lonely Reef have had some of their inflation reduced; the Falcon has been the subject of an unpleasant episode; and the Shamva has shrunk in valuation to something nearer its merits. This mine was bought for £65,000 and transferred for £400,000; as soon as the Company was formed, the 500,000 shares were kited to £5½, on optimistic reports and market juggling, to drop to £1¾ now that the mill is about ready to start. The Globe & Phoenix is still the largest producer, yielding 10,500 oz. gold per month, but it has been rendered ridiculous by a fight over directors' fees and by the squabbles among cliques and coteries of shareholders. At the end of 1913 there is talk of a revival in Rhodesian mining, meaning a renewed outburst of speculation, by reason of the proximate beginning of profitable production at the Shamva, Cam & Motor, Antelope, Falcon, and Eileen Alannah mines. Of these the Cam & Motor is much the most promising; whether the others will justify the expectations now entertained, we doubt. However, the increased yield of gold from these properties will be a stimulant to the market in 1914.

The downward trend of quotations is seen by the following list, of which it can be said now that not one depreciates the true merits of the mines:

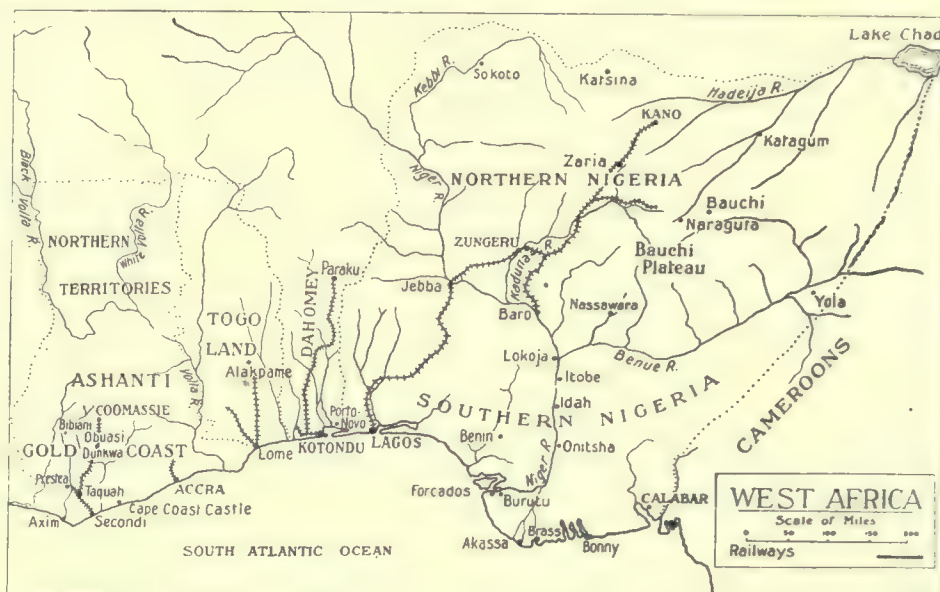

| | Dec. 1, 1912. | Dec. 1, 1913. |
|----------------------|---------------|---------------|
| Cam & Motor..... | 37s. | 28½s. |
| Shamva | 3¾ | 1¾ |
| Globe & Phoenix..... | 1½ | 1¼ |
| Falcon | 1¼ | 7½ |
| Eldorado | 1¾ | ¾ |
| Lonely Reef | 3 | 2¼ |
| Giant | 1½ | 5½ |
| Chartered | 26½s. | 19s. |
| Tanganyika | 2½ | 1¾ |

Of the two chief copper enterprises, the Bwana M'Kubwa was the victim of a fiasco, due to an erroneous assumption of the specific gravity of the ore, and still has to face sundry metallurgical uncertainties, while the more famous Tanganyika Concessions has two blast-furnaces in operation at Katanga, producing about 900 tons of copper per month. Fine ore is being briquetted, and the Company is making its own coke at Wankie. However, the performance seems small enough after the big promises of four years ago.

One of the events of the year has been the effort made by the British South Africa, usually called the Chartered company, to develop the agricultural resources of Rhodesia, by encouraging immigration and settlement on the land. This promises to help many of the land companies, and some of the mining companies that own land. It is a commendable departure,

and ought to prove generally beneficial to industry in Rhodesia. Unfortunately the proposed alienation of the land to newcomers is meeting with opposition on the part of the resident white population, and threatens to make trouble for the Chartered company.

West Africa.—This part of the world, from the miner's standpoint, is now divisible into the Gold

Coast and Northern Nigeria. All the enthusiasm of early exploration has died out of the Jungle market, as the West African gold mining department is called. The annual output of gold, estimated at £1,630,000, shows a small increase, but it has become realized with regrettable tardiness that the cost of operations under conditions so adverse to white men has been underestimated all along. A good example is afforded by the Prestea, a splendid gold-quartz vein, where the yield was estimated repeatedly at 40s., as against a cost of 20s., per ton. After several years of disappointment it is clear now that the yield is 33s. per ton, while the cost is 26s., so that the net resultant profit is about 7s. as against the roseate predictions of 20s. per ton. The Ashanti Goldfields is doing well, both as to output and dividends, but here also expectations are now on a lower and less flamboyant plane. The Broomassie is doing better, but far below the promises of its prospectus. The Bibiani has joined the Cinnamon Bippo, Effuenta, Fanti, and other 'has beens' of the insalubrious jungle. Of the mines on the banket, once supposed to give the promise of a second Rand, the Taquah and the Abosso are both creditable enterprises, but the margin of profit is small. The Abbontiakoon, which resumed crushing in the second half of 1912, has steadily increased its output, but the inability to reduce the cost is a severe handicap. Two dredging companies, on the Offin and Ancobra rivers, respectively, manage to make a profit, but this is done under difficult conditions, both as to submerged timber and unfavorable climate. No new enterprises of any consequence are coming forward, so that an expansion of the gold min-

ing industry in West Africa is unlikely. A few comparative quotations are appended:

| | Dec. 1, 1912. | Dec. 1, 1913. |
|--------------------------|---------------|---------------|
| Ashanti | 21s. | 17s. |
| Prestea | 17½s. | 13s. |
| Abbontiakoon | 6½s. | 6s. |
| Taquah | 13s. | 14s. |
| Abosso | 20s. | 18s. |
| Broomassie | 5½s. | 5½s. |
| Offin River | 5½s. | 4½s. |
| Fanti Consolidated | 8s. | 5s. |

Tin mining in Northern Nigeria is making progress, as is indicated by an increase of production and the more systematic exploitation of the alluvial deposits. As yet no veins or lodes of any importance have been uncovered. The output is the yield mainly from 'calabashing,' or panning, of rich patches of gravel by native workers, who are paid from 1 to 6 pence per pound for the tin concentrate. Ditches and pipe-lines are under construction by several companies, notably the Naraguta, Naraguta Extended, Rayfield, Bisichi, Ropp,

machinery. Most of the tin so far exported has been carried on the backs of natives. The construction of railways is being pushed with commendable zeal. The present railway runs from Lagos to Kano; the branch line to Rahama is being continued to the Bauchi plateau (which is the tin region), leaving the main line at Zaria and terminating at Bukuru. In addition, the Government proposes to construct a more direct line from the mouth of the Bonny river, where deep water is available, through the Udi coalfield, across the Benue river, along the edge of the Bauchi plateau, to Kaduna, where it will join the existing railway. This line will be 530 miles long and will shorten the distance from the mines to the coast by fully 160 miles.

The following quotations indicate a fairly vigorous market in Nigerian tin shares:

| | Dec. 1, 1912. | Dec. 1, 1913. |
|-------------------------|---------------|---------------|
| Rayfield | 16s. | 11s. |
| Naraguta | 13s. | 13½s. |
| Naraguta Extended | 11s. | 13s. |
| Ropp | 3¼s. | 6½s. |
| Kaduna | 1¼s. | 7s. |
| Bisichi | 1¼s. | 1½s. |
| Jos | 6s. | 7s. |
| Champion | 7s. | 8s. |

America.—This part of the London share-market includes Canadian, Mexican, and South American mines. It is nothing like so important as it used to be before the Rand and Western Australia came into prominence, and in the days when the Exploration Company was so active in the Rocky Mountain region. The Treadwell group, in Alaska, has an agency with the Exploration Company, and the three mines on Douglas island continue to do particularly well, but share-dealings are small, as is apt to be the case with mining of this consistently satisfactory character. The Granville company, formed in 1911 to exploit large alluvial areas along the Klondyke valley, in the Yukon, has undergone re-organization, the interests formerly controlled by A. N. C. Treadgold and J. W. Boyle being respectively incorporated under the names of the North West Corporation and the Canadian Klondyke company. Both the former controllers remain as general managers, and active dredging operations have been under way during the past season, with results considered quite satisfactory. Another dredging company, the Oroville, which started as a Californian enterprise, has gained renewed life by the acquisition of an alluvial area at Pato, in Colombia, where a dredge has been at work since March with highly satisfactory results, the digging of 315,000 cubic yards during the past 8 months having yielded \$205,000 worth of gold. So far, the digging has done considerably better than the drill-holes.

Another enterprise, involving dredging together with land reclamation is the Natomas Consolidated, the bonds of which, to the amount of \$15,000,000 were issued in 1910. After three years it has been acknowledged that more working capital is required and a reconstruction for that purpose is imminent. The

CLEANING THE TIN IN NIGERIA.

and Kaduna, while two companies, the Jos and the Benue, have just begun to work with dredges. If the latter are successful, it will be an important advance, but I am not hopeful as to the correctness of the procedure, because the clay, irregular bedrock, and patchiness of the alluvium all militate against effective dredging operations.

The output in 1912 was 2532 tons of concentrate, averaging about 70% metallic tin; for 1913 it is probable that the production will be 5000 tons of a similar product. The largest producer is the Naraguta, which ships from 60 to 75 tons of concentrate monthly to England. The Rayfield sends from 40 to 50 tons, the Naraguta Extended from 25 to 40, and the Bisichi from 25 to 36 tons per month. A good deal of this concentrate goes to the smelter at Bootle, near Liverpool, erected by Richard Pearce and his son, Frank Pearce, formerly at Denver, Colorado.

Scarcity of labor, as yet, has not become a discouraging factor, but the competition between the companies, with offers of higher wages, may render the position acute unless restraint is exercised. Lack of cheap transport, of course, has hindered the introduction of

yield from dredging has fallen short of the \$5,000,000 estimated by \$2,000,000. In the land business also excessive liabilities have been incurred. However, the fiasco is more surprising than conclusive, for the resources of the Company are enormous and only require a little less flamboyancy in administration.

In Colorado the Independence, at Cripple Creek, is now near an end, the profit coming entirely from the milling of the old dump; in the same way the Camp Bird, after a fine career, is known to be finally exhausted, the Company owning it having transferred its energies to the Santa Gertrudis, a silver mine in Mexico, and the Messina, a copper mine in the Transvaal. A further deal involving the Bonanza and Siempre Viva mines, in Nicaragua, is being incubated in the interest of the Camp Bird, which is now practically a holding company for blocks of shares in various mines. The Tomboy, also in Colorado, is doing well, and has added another chapter to a record of wise management and honorable administration. The Tomboy itself, and then the Argentine, were acquired and worked out; now the Company is operating the Revenue or Montana claims, in the same district, and is making a profit of \$275,000 per annum from a property that cost \$400,000 only.

As regards Mexico, the El Oro district is the most important to the London market. There, the parent mine, the El Oro Mining & Railway Co., continues productive on a diminishing scale, without any prospect in depth. The Esperanza and the Mexico, the two adjacent mines on the same vein system, have depreciated greatly in value, despite sundry discoveries underground that seemed to postpone the day of exhaustion. The Dos Estrellas, on the other side of the hill, has gone the way of most mines that are boomed on the Paris bourse. At Pachuca, the Santa Gertrudis also has had a bad time, aggravated by the belated manner in which information was given to the shareholders. Below the 18th level the lode is distinctly poorer, and the 20th level, now being extended, is yielding results indicating further impoverishment. Meanwhile cross-cuts on the upper levels are finding branch veins, and parallel orebodies of considerable promise, so that lateral development in this mine, as in others, may lead to the development of fresh resources of decided importance. The Buena Tierra, Avino, Mazapil Copper, Palmarejo, Barranca, La Fé, and other mines operated by British capital have been shut down owing to the condition of anarchy in which Mexico has been passing during the past year. New issues have been few. The Reforma mine at Campo Morado was examined for the Camp Bird people, but, for sundry reasons, one of which was the political unrest, it was dropped. A new company, financed by a prominent South African operator, Hans Sauer, was formed to take options on various properties at Pachuca and in Oaxaca, but nothing important has resulted as yet. As soon as the country is quieted, I expect to see a notable stimulus to British participation in Mexican mining, but quiet is a word that ill

consorts with Mexican affairs at the present time. The trend of quotations is shown herewith:

| | Dec. 1, 1912. | Dec. 1, 1913. |
|-------------------------|---------------------|---------------------|
| Alaska Treadwell | 8 $\frac{7}{8}$ | 8 |
| El Oro | 17s. | 14s. |
| Esperanza | 2 $\frac{1}{2}$ | 1 |
| Mexico Mines | 7 $\frac{1}{4}$ | 5 |
| Camp Bird | 23s. | 14 $\frac{1}{2}$ s. |
| Santa Gertrudis | 1 $\frac{1}{2}$ | $\frac{7}{8}$ |
| Oroville Dredging | 5s. | 11 $\frac{1}{2}$ s. |
| Tomboy | 1 $\frac{1}{2}$ | 1 $\frac{3}{8}$ |
| Granville | 14 $\frac{1}{2}$ s. | 10s. |
| Casey Cobalt | 2 $\frac{5}{8}$ | 2 $\frac{1}{8}$ |
| Cobalt Townsite | 3 $\frac{5}{8}$ | 2 $\frac{1}{4}$ |

Several Cobalt issues have been prominent in the share-market, notably the Cobalt Townsite, Casey Cobalt, Cobalt Lake, and City of Cobalt. The last mentioned is a wild project. The first two are controlled by Rose & Van Cutsem, London brokers of good repute. Their mining operations in the new year are to be guided, I hear, by D'Arcy Weatherbe. When the Townsite was taken over, it was thought at Cobalt that British speculators had been 'handed a lemon,' but events have proved quite otherwise, the exploratory work carried out by the manager, A. C. Bailey, having been highly successful. While these calcite stringers, full of native silver, are not well adapted to joint-stock operations, it must be confessed that the public, so far, has not done badly out of Cobalt; but the danger of fallacious expectation is ever present in the case of deposits of such a character. Incidentally, it may be noted that the Associated Gold Mines of Western Australia has an option on the Keeley mine, in South Lorrain, and this option is likely to be exercised, the exploratory work conducted under the direction of J. Mackintosh Bell having been remarkably successful. More recently the same Company has taken an option on the North Thompson property, at Porcupine. This adjoins the Hollinger and the Crown Porcupine. The Hollinger itself had had a small hold on British interest, which has been rewarded, but participation in the development of Porcupine has been scant, owing to untoward happenings three years ago. However, several English companies have scouts in Northern Ontario, and the Kirkland Lake developments are likely to stimulate organized prospecting in the Canadian Northwest.

Australasia.—This part of the world has been prominent on the Stock Exchange by reason of the activity in Broken Hill shares. The great Barrier district in New South Wales, famous for its silver, is now one of the leading sources of zinc and lead supplies. Flotation processes of concentration have enabled ores formerly regarded as inextricably refractory to be separated into their constituent metallic sulphides in the form of various marketable concentrates. During the past year a selective method of flotation has further facilitated profitable treatment. Meanwhile, the big orebodies give signs of continuity. The parent mine, the Broken Hill Proprietary, has an ore reserve still

Among other noteworthy incidents in other parts of the island continent I may mention the passing of control in the famous Mt. Morgan from the estates of the Hall brothers to W. K. D'Arcy and the firm of Lionel Robinson, Clark & Co. A block of 350,000 shares was involved in this transaction, which is the first step to a complete re-organization, under the resident management of Benjamin Magnus, who succeeds G. A. Richard, so long associated with the success of the mine, which is now an important producer of copper, as well as gold. In Queensland also are the Mount Elliott, Great Fitzroy, and Hampden Cloncurry—all copper mines. The former is now deeper than the rich orebody to which it owed a brief prominence, the second is still struggling with the application of flotation to a low-grade complex ore, while the third has suffered from labor troubles and a fire. Another copper mine, the Mount Oxide, has been registered as an English company and is likely to do some good, having rich orebodies and an energetic management. The London control, however, is market-wise and not one to inspire public confidence.

MINING CLAIMS AT BROKEN HILL.

West Australian mines are less prominent, owing to the decline of the big producers at Kalgoorlie. But it must be admitted that they are dying hard, and are being managed with a care unknown in the bonanza days. The Golden Horse-Shoe, Ivanhoe, Great Boulder, Lake View & Star, and Kalgurli are still very much 'on the map,' and in the outside districts the Sons of Gwalia and Great Fingall evince signs of vitality. The discovery of a rich but erratic orebody in the Victorious mine at Ora Banda created some excitement for holders of shares in the controlling company, the Associated Northern Blocks, and the beginning of milling operations in the Bullfinch Proprietary, the sole survivor of a wicked boom, has been another cheerful incident.

The leading quotations reflect the local situation:

| | Dec. 1, 1912. | Dec. 1, 1913. |
|-------------------------------|--------------------------------|-----------------------------------|
| Broken Hill Proprietary | 45s. | 34s. |
| Broken Hill South | 8 ³ / ₈ | 7 ³ / ₈ |
| Broken Hill North | 7 ⁷ / ₈ | *2 ¹ / ₂ |

| Hampden Cloncurry | 2 ⁵ / ₈ | 1 ¹ / ₂ |

*Capital increased from £200,000 to £600,000 during the year.

Three promising mines have been shut down owing to metallurgical difficulties, namely, the Gwalia Consolidated, Lancefield, and Yuanmi. The first of these yielded gold to the value of £400,000 down to 100 ft. in depth, when the ore became refractory, owing to arsenic, with graphite. The orebody is said to be 3500 ft. long, and at 500 ft. (according to several bore-holes) it assays 11 dwt. per ton for a width of 36 ft. The Lancefield vein is higher grade, but not so wide. Arsenic and more graphite are here the trouble. At the Yuanmi antimony is the obstacle. These three properties offer a big chance to metallurgical ingenuity.

The worst episode of the year in Australian mining has been the debacle of the Great Cobar. The £5 shares once quoted at £12 (making the valuation £2,238,504) are now at 18 shillings, and they are not worth that. It is an old story. The purchase price of the mine was much too high, the promotion loot was too big, the working capital was entirely inadequate. Seven years of toil and trouble, varied by one dividend that ought

not to have been paid, have now ended in a recognition of some of the facts, with a debenture debt of £725,000, and a mine that looks feeble on the bottom levels. A fine property has been irretrievably despoiled. The Waihi, which furnished the sensation of 1911, shows no real signs of recovery. Labor troubles have hindered deeper exploration, which so far has yielded no results of importance, only assays that have caused the quotation to rise to an unwarrantable extent.

Russia.—Anglo-American enterprise continues to be both prominent and successful in Siberia, notably in copper mining. The Kyshtim, with which Leslie Urquhart, H. C. Hoover, and A. C. Beatty are prominently identified, has developed into a big property. R. Gilman Brown is the consulting engineer. According to his latest report, the total reserves in October amounted to 2,054,000 tons of assured ore and 397,000 tons of probable extensions. The average copper content of the ore being smelted, at the rate of 600 tons per month, is 3%. The output for 1914 is estimated at from 9000 to 10,000 tons of blister copper. Drilling has been a prime factor in discovering and exploring the various orebodies, of which there are four groups, constituting as many mines. The smelting plant includes the most up-to-date equipment, including an electrolytic refinery. The Hoover-Beatty interest in Atbasar has passed to the Spassky, which is administered by Ehrlich & Co., and includes a French interest headed by E. Carnot and F. Robellaz. E. T. McCarthy is the consulting engineer. The mine has just been deepened to 630 ft., where a cross-cut has penetrated the lode, exposing ore averaging 12% copper. The main orebody of the mine is 250 ft. long and 30 ft. wide, while the smaller orebody is 30 ft. wide for a length ranging from 80 to 120 ft. The average output runs 20% copper, chiefly in bornite, but the second-class ore, averaging 8%, is being accumulated, pending the completion of the concentrating plant. Dividends of 35% have been paid on a capital of £595,330, increased by the absorption of the Atbasar to £950,000. The production of copper is from 400 to 450 tons per month. So far 21,000 tons has been produced. At the Atbasar the previous exploration by boring is being fully verified by systematic development. The ore is a sandstone impregnated with bornite, yielding an ore averaging 8% in copper. The workings are shallow—only down to 250 ft.—owing to the fact that the deposit conforms with the dip of the strata. The erection of a smelting and concentrating plant is under way; when completed, a production of 500 tons of copper per month is anticipated. The resident manager is H. C. Bayldon, who is said to be doing excellent work.

Another promising enterprise is the Tanalyk, which, in 1912, acquired the property of a Russian company operating in the southern Urals. The control is nearly identical with that of the Kyshtim. A debenture issue of £200,000 was made recently for the purpose of completing the equipment, capable of treating 220 tons of ore per day and producing 1500 tons of copper per annum. As yet this is only a large and promising pros-

pect. The chief mine of the group is the Mambet, only 165 ft. deep, exposing a lode 10 ft. wide, assaying 2 to 3% copper, with 8 dwt. gold, and 10 oz. silver per ton. The first unit of the smelter to be ready in London.

The Sissert, which is also in the Ural mountains, was placed on our market in 1912, and since then has been quietly developed by means of bore-holes and mine workings, while increasing its production of copper to about 100 tons per month. Dividends of 10% are being paid on the capital issued, namely, £600,000.

The gold mines are not doing so well. The rich alluvial ground of the Lena Goldfields is being exhausted, although the returns do not show it. During the past season 820,189 cu. yd. of gravel was washed for a yield of £1,424,468, or an average of about 8 dwt. gold per yard; in 1910 the yield was £1,551,849 from 748,896 yd., or an average of 10 dwt. per yard. The cost is 25s. or about 6 dwt. per yard. The Company bought £82,880 worth of gold from its employees. Owing to Russian control of the management, the English shareholders get scanty technical information. The Consolidated Gold Fields, once the principal shareholder, sold out most of its holding long ago at about £4. The shares are now at £2. An effort to introduce American technical methods failed. A recent inspection by C. W. Purington may presage sundry technical improvements. Meanwhile the surrounding region has been investigated by several American and British engineers, with a view to new enterprises, but the remoteness of this Bodaibo district is a severe handicap. According to late advices, a railway is to be built down the Lena valley from Irkutsk.

The Orsk Goldfields is not doing any good. In 1912 the gold extracted was worth £36,662, as against an operating cost of £10,509, but the administration, royalty, maintenance in winter, and London expenses reduced the illusive profit of £26,154 to a loss of £3144. In the same way the Troitzk had an operating profit of \$7800, but a real loss of £600. These theatrical statements of profit are ridiculous. The plain fact is that both mines are being worked at a loss. No new gold-mining enterprises in Russia have come into prominence during 1913, but a great deal of scouting has been done by a number of engineers experienced in Russian conditions, and I anticipate that some of this search will result in new business.

†Old capital, £595,330.

‡New share capital, £950,000.

The Indian gold mines, on the whole, have given satisfactory results, and the output has been maintained. The Mysore continues its run of uninterrupted prosperity, which began in 1888, and the work-

ings at 3500 ft. vertical show no signs of exhaustion. The yearly output is maintained at about \$4,500,000, and the total since the commencement has been about \$75,000,000, of which nearly one-half has been distributed in dividends. The mine has four years reserves in hand. The Champion Reef is not the mine it used to be, for the grade fell away five years ago. At various points rich ore is still found in the deepest levels, and the average has slightly increased during the last year or two. The Ooregum is in a more satisfactory condition than a year ago. Early in 1913 the developments at the Nundydroog were so discouraging that the output was reduced, but toward the end of the year an improvement took place, and the old rate of output was restored. At the Balaghat search is still being made for another shoot of ore, but without success so far. Exploration of the southern continuation of the lode outside the Mysore company's ground is being undertaken from the 2385-ft. level of the Mysore. The exploitation of this ground from the surface many years ago gave indifferent results. During the year several cyanide and slime plants have been erected in the Kolar goldfield, but as the proportion of gold not caught by amalgamation is small, the new plants will not increase the output to any important extent. It is worthy of record that the cost of mining has been greatly reduced of late years, chiefly by the introduction of electric power instead of wood-fuel.

As regards other Indian goldfields, the Anantapur in Madras has arrived at the profitable stage, for a small dividend has been paid by the North Anantapur company. The developments of the adjoining Jibutil property are sufficiently encouraging to warrant the provision of additional capital to provide a treatment plant and to continue developments on a large scale. The mill commenced work in November. On the Ramagiri block, in the same district, a promising ore-shoot has been disclosed, and probably a company will be formed to develop it. The Hutti mine in Hyderabad is making a good showing in depth after passing through a disappointing period. Here the 2140-ft. level contains a rich orebody. The Mangalore mine in the Raichor district of Hyderabad has proved a failure, and is closed. In the Shimoga district of Madras, additional capital has been subscribed for developing the two mines, which are to be worked conjointly.

In Cornwall the position of affairs in connection with lode-mining is far from encouraging. At Dolcoath the deep levels tapped by the vertical shaft are in ore of less than the average grade of the last few years, and the yield of black tin is less than it was a year ago. The seriousness of the outlook is recognized by the management, as is evinced by the fact that parallel lodes are now being explored. The difficulty of maintaining an output of profitable ore has once more been experienced at Carn Brea & Tincroft, and it has been necessary to close the Carn Brea section and devote sole attention to North Tincroft as the most hopeful ground for the discovery of future sources of supply. The grade of the ore at South Crofty is giving anxiety

to the shareholders. At East Pool additional capital has been provided by Bewick, Moreing & Co. for the purpose of pushing development work. This firm has also taken in hand the Phoenix mines in East Cornwall. At the Levant there is some doubt whether the present Company will renew the lease, for the landlords are asking onerous terms and say they have received more favorable offers from another party. The Botallack, which was re-opened six years ago, has proved a dire failure in spite of repeated supplies of working capital. We may hear of its suspension at any moment. The Wheal Jane, near Truro, owned by the Falmouth Consolidated company, has just been closed; three years ago the chairman grandiloquently asserted that there was sufficient ore to keep 1000 stamps going. The only lode mine that can be said to be doing well and to have encouraging prospects is the Grenville, though mention should not be omitted of the improved outlook at Wheal Kitty. If this article

IN CORNWALL.

had been written several months earlier it would have been possible to refer to the Geevor as a bright spot, for ample ore reserves had been developed and a modern dressing-plant erected involving the use of many new machines invented in America. But as the board has made a clearance of this plant for reasons that are no reasons at all, it is necessary to moderate our enthusiasm.

The most prosperous company at present is the Cornwall Tailings, which is making a handsome profit out of the old dumps at Carn Brea & Tincroft. Owing to the success of these operations, many promoters have sought similar properties. The sand on Gwethian beach at the mouth of the Red river, which has yielded a good profit on a small scale for many years, has been purchased by London interests and is to be worked on modern lines. Another similar tract on one of the creeks feeding Falmouth harbor is also being attacked on a large scale. A third is in the Helston district. In all these cases the material has to be pumped to re-grinding and concentration plant, and they are not in the nature of dredging projects, as might be supposed.

Much has been heard of the exploitation of radium ores in Cornwall during the year, and the Trenwith, near St. Ives, and the South Terras, at Grampound

Road, have both been in the limelight. The published statements show that radium bromide from the pitchblende at Trenwith is finding a market, and the recent great expansion of the use of radium in surgery has brought many inquiries and orders.

Various.—One of the most important features of 1913 has been the growth of interest in tin mining in the Malay States. The excellent results obtained by the Tronoh, Gopeng, Latah, Tekka, Kinta, Pengkalen,

formed in 1911, started its first dredge in January last, and has been recovering 1 lb. of concentrate or 'black tin' (72% metal) per cubic yard. This preliminary work has justified the building of two more dredges, which will shortly be at work. F. W. Payne is the consulting engineer. The Siamese Tin Syndicate was formed in 1906 to exploit an alluvial area in the Renong district of Western Siam. A net profit of £40,822 was earned during the past fiscal year from a gross profit

PUMP DREDGE, SHOWING UNEVEN BOTTOM.

Situpeh, and other alluvial mines in the Kinta district, in the state of Perak, have stimulated interest in that region. Across the border, in Siam, the Tongkah Harbour, Renong, Malayan, and Siamese companies are dredging, in contrast to the sluice and elevator practice in Kinta. The Tronoh is the premier mine, but it has passed its zenith. Last year 496,495 cu. yd. was washed with a yield of 12½ lb. black tin per cubic yard. The alluvial practice common to the Kinta district is to be supplemented at Tronoh by the introduction of bucket-dredging, on the suggestion of H. D. Griffiths, who has recently resigned as general manager. At the Trekka the ground is hydraulicked, while at the Taiping, also belonging to the Tekka company, a suction-pump dredge is used. The Malayan Tin Dredging Co.,

of £58,395. This was done with one dredge. Two more have been ordered. H. G. Scott is the manager. The Renong Dredging Co. has made a great success with the dredge erected in 1910. Two more dredges are about to start, and additional ground has been acquired. To do this the Company has been reconstructed, and £28,000 more capital obtained. It is estimated that a profit of £50,000 per annum can be earned when the three dredges are at work. Last year 682,986 cu. yd. was dredged with an average yield of 14 oz. black tin per yard, at a cost of 4.41d. per yard, but the total cost (including an export duty of 1.7d. per yard) was 6.07d. E. T. McCarthy and F. W. Payne are the advisory engineers. Recently a number of new dredging companies have appeared, such as the Ipoh and Kamun-

ting, both under good auspices. On the whole, this growth of the tin-dredging industry in the Malay peninsula is likely to prove a highly successful phase of Far Eastern development.

Lode mining as yet is represented only by the Pahang, on the east side of the Malay peninsula, an old enterprise with a chequered career, brightening of late. In the year ended July 31, 1913, the output was 1125 tons of black tin from 102,797 tons of ore, treated in a 50-stamp mill. In addition, 115 tons of alluvial tin was

experiments are made with a view to treating the second. The largest shareholder is R. Tilden Smith, and the managing director is H. C. Hoover. Recently C. H. Macnutt was appointed resident manager.

In South America the resuscitation of the old Quebrada copper mine, near Aroa, in Venezuela, is interesting. The first Company went into liquidation in 1895. W. A. Heywood, at one time of the staff of the old Company and known for his work at the Tennessee Copper, is the metallurgical advisor. A new smelter is

being erected. The new Company, the South American Copper Syndicate, has already paid handsome dividends on a reduced capital by making shipments of rich ore. The St. John del Rey in Brazil continues its honorable career, producing nearly £400,000 worth of gold from 165,000 long tons and paying about £70,000 in dividends yearly. The workings are 5200 ft. vertical and 7300 ft. deep on the dip of the lode. Besides the Pato dredging affair, I may mention the Anglo-Colombian Development Co., organized by the Consolidated Gold Fields to exploit platinum deposits of alluvial character in Colombia. This is said to promise well. On the whole, the amount of British capital now embarked in South American

THE NORTHERN PORTION OF SOUTH AMERICA, SHOWING PATO AND AROA.

recovered. The maximum depth of the working is 800 ft. Far north in the Shan States, of Burma, the Mawchi company is about to start its new mill, having a capacity of 100 tons per day on a reserve of 107,000 tons of ore, valuable for its tin and wolfram contents. The mine is young, and full of promise. Farther toward the Chinese border is the property of the Burma Mines, a company organized in 1906 to benefitiate the old slag-dumps found in the jungle, and supposed to have been made in the extraction of silver from a lead-carbonate ore. While the slag was being extracted and smelted (first at Mandalay and then at the mine) the ancient workings in the vicinity were investigated and explored. Recent development, by adits, has proved the existence of an enormous orebody, containing 23% lead, 26% zinc, and 25 oz. silver per ton, with traces of copper. Old workings indicate that this orebody is 2500 ft. long; it has been proved underground for 750 ft., and averages 50 ft. wide. Another lode containing 8 to 10% copper, 10% lead, 10% zinc, and 10 oz. silver, from 7 to 8 ft. wide, has been discovered. According to late advices, it is as much as 35 ft. wide, assaying 14% copper. Here we have two of the finest orebodies uncovered during the last decade. The copper ore is docile, while the other is intensely refractory; hence the exploitation of the first will furnish funds while

can mining is quite out of proportion to the interest once taken in that sub-continent. The following quotations require no further comment:

| | Dec. 1, 1912. | Dec. 1, 1913. |
|-------------------------------------|---------------|---------------|
| Dolcoath | 25s. | 17½s. |
| Cornwall Tailings | 1½ | 7½ |
| Gopeng | 1½ | 1½ |

| Ooregum | 18s. | 22s. |
| Champion Reef | 12s. | 10½s. |
| South American Copper Syndicate.... | 34½s. | 32s. |

Apart from changes in the mines themselves, the year has been marked by general unrest in the ranks of labor, accompanied by scarcity in the supply of that prime instrument of exploitation. The growth of world-wide industry is making ever increasing demands for labor and the spread of what is called civilization tends to teach the subject races to ask for higher wages. Meanwhile, white labor becomes increasingly exacting. Hence trouble. To overcome this obstacle, the inventive genius of man must be supplemented by a humane effort to alleviate the drudgery of toil.

Are we not now beginning to feel the part depletion of our principal? Our great West is not as it was, a vast empire where there was always room for the man who would try. We can no longer relieve our own congested centres of population by the mere slogan that there is a quarter section of land to be had for the asking. We are beginning to feel a little pressure here and there, and not having been used to it, there is the spendthrift's unwillingness to unpleasant facts. With all our riches, there has come a capacity to enjoy and a forgetfulness of the necessity for self denial, and an extravagance that manifests itself in ways that are a little disquieting. Automobiles and

It is to such fundamental conditions as are here meant to be roughly outlined, that present day market conditions are due. The huge demands for capital represent increased needs due to the complication of urban existence. The difficulty in meeting such demands is due at least in no small degree to the fact that our percentage of actual producers has relatively decreased and that a correspondingly larger proportion of both labor and capital are engaged in an endeavor to supply the needs of communities, rather than in the work of the actual production of wealth. Huge sums

are demanded for city needs; water works, electric light and power plants, urban and interurban transportation, for railway terminals. As a nation, we have been indulging in an era of extravagance; we have been vastly increasing, multiplying our overhead expense; and this probably has little more justification than the similar tendencies of the individual, who has wondered why he finds himself unable to maintain an automobile or two and increase his savings bank balance at the same time.

To treat of the market itself, it almost suffices to say that stagnation has ruled. The happenings of the year were not at any time such as to induce any large public participation. The death of J. P. Morgan in February left the New York money centre without the leader to whom it had looked for many years, and the opening of the new year has not as yet revealed his successor. In May the St. Louis & San Francisco Railroad Co. was placed in the hands of the courts and the revealments of its inside operations have not so far been of a nature

ALASKA PERSEVERANCE MINE, THE NUCLEUS OF THE ALASKA GOLD MINES PROPERTIES.

to reassure security holders. Later, the New Haven debacle furnished much argument and justification for those who have criticised so-called 'high finance,' and it left New England dazed and indignant. All through the year the troubles of Mexico have threatened to involve the United States and whether or not of real effect upon stock market movements, they have served continually as excuse for, or cause of, this or that prevailing market attitude.

In the world of mines and mining, conditions have been peculiar. Following the era of undue and unwarranted speculation of some years ago, mining share markets throughout the East have fallen into a rut from which it seems almost impossible to dislodge them. The results achieved by the porphyry coppers, for which the public has shown marked favor, form an exception; as does also the latest example of the public preference for large enterprises, the successful launching of the Alaska Gold Mining Company.

A very peculiar situation as to mining properties exists now in New York. There is an insistent demand for anything that is close to the point of production, but it is next to impossible to interest the same people or the public in anything that has to be classed as a

prospect. In a way this attitude is faulty as it overlooks the necessity for primary development, which requires some capital which, while it, in the majority of cases will probably be spent without return, need not be relatively large. It seems to be temporarily forgotten that there is always the possibility of the development of ground that will pay many times for all the previous fruitless efforts and expenditures.

In copper, the trend except toward the close of the year has been to give to the producer more and more the control of the metal market. The ravenous appetite of the commercial world for copper metal resulted in the reduction of the world's visible supply to a negligible quantity. However, the strength of the statistical position became apparent only at that juncture in October, when the business attitude was overwhelmingly and generally one of hesitation. There was a marked reduction from about 17c. per pound to 14½c. per pound notwithstanding the fact that supplies were smaller than at any time since the Producers' Association began to collect and publish figures covering production and consumption. A sharp reaction and higher prices may be anticipated if the turn of the year brings with it any resumption of normal activity. The year just closed saw a further growth of the Guggenheim organization in the field of copper production. The recent development of the Chile Copper Co. marks its deposit as possibly the largest copper deposit in the world now being mined. Unofficial estimates mention between 200,000,000 and 300,000,000 tons of ore of more than 2.5% copper content. This new development of the Braden coupled with the possibilities of this Chuquicamata deposit of the Chile Copper Co. promise the Guggenheim group a commanding place in copper output.

Eastern markets have shown a minimum of activity in precious metal issues. What trading has been done in Tonopah issues has been of a distinctly professional character with almost no interest manifested by outsiders. While Cobalt has surprised all those who have followed the history of the district and noted that it has maintained its production and marked another record for bullion output, there has been but very slight market interest in Cobalt shares. The Eastern markets remain, so far as mining shares are concerned, in a waiting attitude. Could there be opened a new precious metal district of real merit, the call for funds would be eagerly and generously answered. Until some such fortuitous discovery can be heralded, it is safe to anticipate continued apathy, though at the same time the market for partly developed properties was never better, and mining activity, apart from the share markets, never greater.

The details of the year's markets are perhaps sufficiently well shown in the accompanying charts. It will be noted that prices of shares in railroads, industrials, and mining companies have moved together and that all suffered alike a sharp decline in June and a temporary recovery in September, and that prices in December were much lower than in January.

Business and Mining—A Retrospection

By F. LYNWOOD GARRISON

At this season of the year when a business man is disposed to review the past and take stock of achievement many pertinent thoughts arise in the mind regarding the future of the particular occupation by which one's daily bread is earned. Indeed, this is the paramount question as long as life lasts, hence any facts regarding it which are more than commonplace, are certain to be of interest.

We note among other things numerous communications in the technical press asking why mining is languishing and whether prospecting has become a lost art; moreover one's mail is often not a little burdened with appeals for work from fellow engineers. It is impossible not to be impressed by the evident seriousness of this condition and it seems eminently proper and timely for us now to seek some of the causes that have led to it:

Capital on the Defensive

Statistics will probably show that on the whole mining is not decadent, quite the contrary in fact, for the output is greater and profits probably not less than last year. Conditions, however, are rapidly changing all over the world. The exactions of labor are greater and in this country at least, the insistence of the tax collector is much more pronounced. Such factors bear with increasing weight upon the operator, especially the small one, and capital is put on the defensive, a condition which inevitably results in combination. Once upon a time the railroads squeezed the weak and gave rebates to the strong. Now it is their turn to be punished, to the loss thousands of unfortunate stockholders who may have put life savings into their capital stocks, knowing that they are the arteries of trade and what hurts the transportation companies, injures the whole country; hence of all classes of investment, they should be under normal and logical conditions, as safe and sound as government securities.

Next to agriculture, mining is our second great basal industry; modern civilization cannot exist for a moment without it. With hydro-electric power we may mine and smelt our metals; we can, at a pinch, do entirely without fuel if we have hydro-electric power, but without metals we cannot generate and transmit this form of energy. In brief, we are a metal-using people and will revert to savagery without it. We must mine to get metal and mining will not cease as long as there is any metal to be got. This brings us to the question—are our mineral deposits being exhausted? The plain answer to the question is that they are, but also that the resources are so enormous and with the probability of much more being developed, we need have little anxiety on this point.

These reflections are so self-evident they are not

likely to be disputed, but they fail to carry us very far. We know, or at any rate believe, something is now wrong with the mining industry as far as we engineers are concerned. What it is and what may be the outlook for the ensuing year are matters which gravely concern us at the present time.

The profession, in common with most of the other engineering pursuits, is undoubtedly over-crowded. The mining industry is not, and has not been, for the past ten years capable of absorbing the multitude of graduates from our mining schools. It is a shame and it is disgraceful to see fine well trained young men, who have spent from four to six years at our colleges eagerly offering themselves for \$75 or \$100 per month and ready to go on such conditions to distant and unhealthy countries. The man or corporation which accepts such terms cannot be blamed, for it is simply a question of supply and demand; moreover, mining companies as a rule consider the comfort and health of their staffs, especially when abroad.

Another factor which is serving to depress the mining business is to be found in the political conditions now affecting Mexico. This unfortunate country is pre-eminently the most attractive in the world to mining men, and deservedly so, by virtue of its matchless climate, its resources, and its propinquity to the United States. Hundreds of American engineers are now out of employment by reason of these disturbances and there appears to be little hope for better conditions within the next year.

The enormous and astonishing development of the oil districts in United States and Mexico cannot fail to check the demand for coal, especially for maritime purposes. Settlement of Mexican difficulties and the rapid development of South American fields will permit fuel oil to be cheaply delivered on the Atlantic seaboard, and our Eastern coal operators will be forced to meet this formidable competition.

The Vanishing Frontier

With Alaska, Canada, the Central and South American countries undeveloped, not to mention Siberia, it seems unlikely any considerable slackening of metal mining may be anticipated due to exhaustion of resources. Moreover it must be evident to at least a few thinking and well informed mining engineers that some of our old districts in the United States are far from being exhausted, and that they will readily respond to the skill of the engineer and no longer remain condemned as worked out by the fiat of the so-called practical mining man. The danger of empiricism in this as in most affairs of life, is that it is always specific; its value depends upon a particular condition or case, it is not general. The practical man is often uneducated,

he knows, or can do, only a few things well, he necessarily has the limitations of ignorance and narrowness of an untrained mind. The value of education has never been more evident than today and perhaps never so inadequately rewarded, suffering by comparison in this respect with the artisan, who exacts more pay for less good work than ever before. The question, therefore, naturally arises—may we not be making technical education too cheap? Whether we are or not, it is certain we have spoiled many good farmers and mechanics in the making of supernumerary and indifferent engineers.

Lessons from Germany

Americans have been accused, and to some extent justly, of being unphilosophical and unduly practical. The most philosophical people in the world are probably the Germans, yet no nation in modern history can show such matchless practical achievement as has Germany within the past 25 years. If we permit prejudice, of which we have much, to have place in or replace our philosophy, we are absolutely certain to find ourselves at a great disadvantage in competition with the Germans, for we will thus discount at every turn the splendid technical training our educational institutions have afforded. It is to be feared we are, as a people, too conservative, even hide-bound and often niggardly and slow in keeping abreast with modern progress.

In our wild scramble for wealth we are sometimes so illogical as to defeat our own ends and even of occasion, have been known to deviate from a course of business honesty and rectitude, which sooner or later brings a just and merited retribution. Dishonest reports and lying prospectuses were never more easily discredited than at present and he who uses them does so at his peril.

If existing financial and business conditions have made legitimate mining somewhat sluggish, it has also put a most wholesome check upon wild-cat promotion and charlatanism. Sound ethics and personal character are as important to success as they ever were in the history of the world. Most of our mining periodicals and professional organizations today respond vigorously to these sentiments. I doubt if any satisfactory code of ethics can ever be devised for engineers. The younger men will be more influenced by what their elders do, than by any decalogue of don'ts. Man is a social animal, social ostracism punishes more effectually and keenly than the jail. If our professional organizations of all kinds rigorously purge their membership of men known to be disreputable or even open to that suspicion, it will be better for the country and for the profession.

Moralizing is tiresome even if needed; we may take satisfaction, however, in the obvious fact that the country is as sound, healthy, and moral as it ever was, even if some of our newspapers are reptilian and many of our so-called statesmen but ignorant boors. We cannot have self government and perfection, or

even economy, for it is ever costly in money and sometimes in self-respect. We elect our rulers from the most plausible talkers; indeed plausibility is their greatest asset and often the only gift some of our politicians possess. At present we are perhaps, as a nation, disordered but not diseased; we have been getting a good many nostrums for imaginary ills. Let us not indulge in a foolish clamor against corporations, for combination of capital will go where the individual fears to tread. All we ask is that both the individual and corporation get a square deal and no favors. But we can never hope to have it as long as we are content to fill big places with small men. Ordinary prudence forbids the placing of untried and untrained men in the management of a large mill or smelter.

Business and Government

The philosophy of government is not different from that of organized business, and it is beginning to become more and more evident that good business and good government must go hand in hand. At present it seems to me we are paying the penalty of indulgence in fads, fancies, and untried theories. Political parties are necessary to our form of government. The Southern states adhere tenaciously to one political party because they must, for reasons which are no way political, but unfortunately the best men of that section do not as of old, become the leaders of this party. I dare say the average American cares little which of the two great political parties are in power, provided he gets good government and his country is not made the laughing stock of a critical world. We can stand high tariff, low tariff, or no tariff at all, but we cannot afford to make ourselves ridiculous. Mistakes of policy or judgment do not shake confidence as does folly, blatant and crass ignorance; this, at the bottom, is what is the matter with mining and is troubling the whole country. We are rapidly getting away from the notion that business should be detached and apart from government. Whether or not we are correct in this assumption is beside the question, the fact remains these two great functions of civilization are growing more and more interdependent—what affects one will react on the other. It therefore behooves us to place our government in the hands of able and experienced men, and not to assume that people unfitted for responsible positions in business can creditably discharge equally important functions in the government service.

The Mexican Eagle Oil Co. reports that in the year ended on June 30 last, over 200 vessels have taken oil at Tuxpam. The facilities now permit the loading of a 10,000 ton ship in 24 hours. Leases have been acquired on 50,000 acres of additional oil lands and 30,000 acres have been bought. A new field was brought in with a 5000-bbl. well and development has been generally satisfactory. The profit for the year was \$8,166,514, which, after allowance for depreciation and fields redemption, left \$4,615,500 to be added to the existing surplus of \$631,805.

Work of the State Geological Surveys

By FRANK W. DeWOLF

The public is appreciating more and more the fundamental value of scientific work by the various state geological surveys. The growing need for accurate inventories of natural resources has brought into prominence the fact that work on the subject has been going on in a quiet way for a great many years. Intelligent development and conservation must, of course, be based on knowledge. While the function of the surveys is chiefly to aid the development of state mineral resources, and in some cases to investigate soils, forest, and highway work, nevertheless a large annual contribution is made to pure science itself.

There are 35 active state surveys, including the new organization created during the year in Oregon. Several of the surveys, however, are embarrassed from time to time by lack of appropriations. Thus the Arkansas Survey was officially inactive during 1913. Altogether, the surveys expended approximately \$475,000 and received the benefit of \$140,000 additional expenditure by coöperating federal bureaus. Over 100 scientists gave full-time service for the states and about 50 others, besides topographers and soil experts, were furnished by coöperating bureaus. Thus the surveys have a large and cumulative influence throughout the country for enlightenment and for scientific development of natural resources. The Association of American State Geologists meets each year during the Christmas holidays, and as a rule, in a spring conference at Washington. Beginning with 1914, field conferences of state geologists will probably be held, so that problems in common can be reviewed in the field, and coöperation between neighboring states can be rendered more efficient.

Organization and Funds

State geological surveys and mining bureaus are organized in one of three ways: (1) under state university control, or with the survey director giving part of his service to the state university; (2) under a commission or board, without university connections; (3) under a chief appointed by the governor, or otherwise independent. Considering the active surveys, 16 belong to group 1 and have financial support averaging \$7500 per annum. Group 2 includes 15 surveys, with annual appropriations averaging \$22,300. Group 3 includes two surveys with average funds of \$5600 per annum. Judging from the available funds, the most successful and active surveys are under commissions, and the directors or managers have no outside demands on their time. Exceptions in this group include two such surveys with funds averaging only \$8500; exceptions to group 1 include three surveys with annual funds of \$15,000 each, and one which receives \$27,500 per annum. Other factors affecting the strength of state surveys include the extent and variety

of the mineral resources of the area to be studied, and in part, the length of time during which the survey has been in operation. Those states with abundant mineral resources and important mineral industries either have very active surveys at present, or have had such service for many decades though the present organization may be poorly supported. Information regarding the mineral resources of the various states can be obtained without cost by addressing the officer in charge, as shown by the following directory:

STATE GEOLOGISTS

- Alabama—Geological Survey of Alabama; E. A. Smith, State Geologist, University.
- Arizona—Geological Survey of Arizona; Territorial Geologist, Tucson.
- Arkansas—Geological Survey of Arkansas; N. F. Drake, State Geologist, Fayetteville.
- California—California State Mining Bureau; F. McN. Hamilton, State Mineralogist, San Francisco.
- Colorado—Colorado State Geological Survey; R. D. George, State Geologist, Boulder.
- Connecticut—State Geological and Natural History Survey; Wm. North Rice, Superintendent, Middletown.
- Florida—Florida State Geological Survey; E. H. Sellards, State Geologist, Tallahassee.
- Georgia—Geological Survey of Georgia; S. W. McCallie, State Geologist, Atlanta.
- Illinois—State Geological Survey; F. W. DeWolf, Director, Urbana.
- Indiana—Department of Geology and Natural Resources; Edward Barrett, State Geologist, Indianapolis.
- Iowa—Iowa Geological Survey; G. F. Kay, State Geologist, Iowa City.

Topographic surveys were continued during 1913 in 14 states, under coöperative agreement with the U. S. Geological Survey, which shares the expense. More than 10,000 sq. mi. was mapped as a basis for geological and engineering studies. A large share of attention, and on an average of about one-third of the geologic funds in the various states, are devoted to economic and detailed areal surveys. Most reports issued describe local mineral resources in such a way as to encourage careful investment. Important deposits of stone and minerals available for building, or for use in cement, concrete, road-ballast, or in the arts, are found in many states. Investigations were made and reports published as follows: The marbles and crystalline rocks of Alabama, and slates of western Pennsylvania were investigated; reports on building stones of the states were in preparation in Minnesota, New York, and Ohio; a bulletin describing the cement materials of Washington was distributed early in the year; a study of limestone and marl for agricultural uses in southern Georgia was in progress; materials available in Iowa for road-building, and for concrete, were tested; the limestones of Michigan were also investigated.

Clay deposits of Colorado east of the mountains, and elsewhere in the vicinity of large towns, were tested and the results were published during the year. Clay materials available at coal mines were examined in Illinois. Practical tests of clays of Kansas were under way, and a study of Minnesota brick and clay industries was completed. Fireclays of Pennsylvania were the object of special study in that state.

The importance of lignite in those western states which have no adequate supply of high-grade coals, has recently been brought to public attention. Investigations of the availability of lignite for gas-producer practice, were continued in western North Dakota and

in South Dakota. A study of coal resources and mining practices in Illinois was continued in coöperation with the University and the U. S. Bureau of Mines, and three reports were issued, including proximate analyses of 350 mine samples. Several folios covering the coal territory were issued in coöperation with the U. S. Geological Survey. In Iowa, a series of ultimate analyses of coals was completed. Tennessee coals north and south of the Tennessee Central Railroad were described, and field work was finished for a report on coals of the state. Surveys of the important coal fields of Washington were continued. Nine reports for counties in the coal fields of West Virginia were either published during the year, or prepared for publication.

The surveys made extensive examinations of developed or prospective oil and gas fields. In California work was begun on a report for the entire state. In Illinois, a report on the southeastern fields was published, and three coöperative folios covering oil territory were in preparation. Michigan issued a bulletin on oil and gas resources. In the Oklahoma field, four parties were engaged in developed or prospective oil and gas territory. The detailed mapping of the Hominy quadrangle was completed in coöperation with the United States. The report on the Vinita and Nowata quadrangle was sent to press. In Washington, investigations regarding oil and gas in the western part of the state were in progress. Six county reports published in West Virginia had special reference to the structural relations of oil and gas. A conference was called during the spring at Pittsburgh between representatives of the various state surveys, of the U. S. Bureau of Mines, and of operators in oil and coal fields, for the purpose of considering the relation of gas exploitation to coal mine explosions. Many explosions have been due to leakage of natural gas into mines. As a result of the conference a model law providing for state inspection of drilling operations through workable coal beds, was recommended to the various legislatures.

Ore Deposits Examined

Surveys of the Platoro-Summitville gold district of Colorado were made. This is the old Summitville district which produced a considerable quantity of gold twenty years or more ago. H. B. Patton of Golden is directing the new work in the district. In Missouri, experiments on the electric potential of minerals were continued, and a study of the Aurora region was in progress. Copper prospects in Pennsylvania were investigated. Eastern Tennessee red-iron ores were described in a coöperative report. A bulletin on the geology and ore deposits of the Covada silver and gold districts in Washington was issued. In Wisconsin, the orebodies in the lead and zinc regions were mapped; and a magnetic survey was begun to outline new iron deposits and to classify the land of the northwestern part of the state for taxing purposes. Detailed areal work, including economic geology to some extent, continued in most of the states.

Although stratigraphic and paleontological studies

do not, at first glance, appear to have great practical importance, they nevertheless are necessary fundamental studies, and they have indirect economic value. Perhaps the most significant move of the season was the 'Mississippian Conference' which was called in the field in Missouri. Eight states sent delegates to the meeting, and the U. S. Geological Survey was represented by David White, chief geologist. A committee

of the state representatives was appointed to direct interstate work, so as to avoid conflict and unnecessary duplication of formation names and of field work. Annual mineral statistics were prepared in nearly all of the states. Bibliographies of great value to mining men were issued in Colorado, Iowa, New Jersey, and in Washington, and studies of road, soil, and other subjects were made in many states.

Zinc Ores and Metallurgy in 1913

By R. G. HALL

The history of the zinc industry for 1913 is not pleasant writing, and while the rôle of Cassandra has ever been a thankless one, it does not need the prevision of a Cassandra to predict a lean period for the ore producer in 1914. The year 1912 closed with a falling market, and a decreasing consumption. The elections of 1912 foreshadowed a marked change in the tariff conditions, especially as related to the steel business, and from a high point of about 7½c. in October, spelter had reached a figure of 7c. early in January. From that point, as may be noted, the recession was gradual until a price of \$4.90 per 100 lb. was reached in June. A recovery from this point was made to \$5.60 per 100 lb. by September, only to be lost again on the passing of the tariff bill, until December sees a price again below \$5. The cause of these fluctuations has not been entirely the tariff on zinc and zinc ores, but rather the general business conditions. It will be noted that at one time the official St. Louis quotations on spelter were practically the same as those of London, even at a time when the duty was still 13½c. per pound, and even today the New York price is still below the import basis, and with the spelter stocks now on hand and yet accumulating, there is no prospect of an advance in the near future. The history of the iron and steel business has always been and always will be the best indication of the history of the zinc industry, and the past three years have afforded excellent illustrations of this characteristic.

Notwithstanding the much decreased prices, the production from the Joplin district has been about equal to that made in 1912. At this writing a total shipment of 'jack' of 280,000 tons and of silicate of 22,000 tons is indicated, these about equaling the record year of 1912, and a much larger stock of concentrate remains in the bins than was there on January 1, 1913. The most potent reason for this condition, of course, is what one might call the inertia of mining. During the period of high prices vigorous prospecting was conducted, and many new mines were opened. These properties, once opened, can hardly be closed without great loss. A long-continued period of low prices such as now prevailing will, of course, forbid the opening of new properties, and matters will right themselves some day. But—and here is the discouragement of the Joplin producer—in the meantime the production of the

Western states, due chiefly to Butte, is increasing even in spite of low prices, and the new tariff conditions have made possible importations of cheaper ore so soon as Mexico shall have settled to a point where mining can be resumed.

Wisconsin also will show a production of close to 72,000 tons of concentrate and carbonate. Colorado maintained its output close to the 1912 record, although some decrease will be shown in Leadville carbonate, as well as from smaller shippers in various parts of the state. Montana production is of course very much increased. At the first of 1913 the Butte & Superior company was marketing about 200 tons per day of 46 to 48% concentrate. The production at present is reported to be close to 350 tons of over 50% grade. The Elm Orlu has not again entered the list of producers, but is expected to do so early in 1914. Utah will show a considerable decrease due to the almost complete suspension of shipments except those from Park City and the United States mill at Midvale. Nevada also will show a decrease, as the Good Springs properties suspended production early in the year. They since resumed to some extent, but not up to the former mark. Idaho continues to produce to some extent, but as the production is mostly made in connection with lead mining it can easily be guessed what will happen under a combination of 4c. lead and 5c. spelter, with a freight rate of \$9.75 per ton to Oklahoma smelters. This gives them a price not much in excess of \$8 per ton for a 40% zinc concentrate on cars in the Coeur d'Alene district.

Zinc smelting in 1913 has not been productive of much cheer for those engaged therein. Even if the price of ore has fully followed down the price of spelter, it is not cheering to watch the shrinkage in the value of your stocks of at least \$1 per ton of spelter per week, and this not for one period but practically every week averaged throughout the year. November 1912 to November 1913 saw a drop throughout of \$50 per ton of spelter. At the same time the margin, as it is roughly figured on Joplin district ores, faded away from about \$18 in the latter end of 1912 to \$10 in December 1913 and at times during 1913, it was even smaller than that. When it is remembered that the works cost to the smelter is generally figured at about \$10, it will be easily figured that the most prob-

SPELTER PRICES, 1913.

able dividends of 1913 will be 'Irish' ones, or at best of the 'New Haven' variety.

The year started with a smelting capacity active in the United States of about 1000 tons per day, and the figures published at midyear by the U. S. Geological Survey showed 180,000 tons produced. As there has been no appreciable decline in production since that time, it is probable that the total production for the year will be in the neighborhood of 350,000 tons as against a production from all sources in 1912 of 338,806 tons. But the stocks of metal on hand during the first half of the year had enormously increased, and it is probable that the stock remaining in the hands of the producers alone on December 31, 1913, will be well in advance of 50,000 tons, indicating a consumption of somewhere in the neighborhood of 300,000 tons, as against 340,341 in 1912. At this writing it is impossible to give these figures with any degree of accuracy.

There have been no advances in the metallurgy of zinc in 1913 as relates to the practical operation of smelting works unless an enforced economy can be considered an advance. Much experimenting was done in electro-thermal smelting, and one experimenter has recently announced his intention of carrying on his work to a commercial basis in the near future. I understand also that work carried out by others gives promise of commercial results in the future, but up to today the amount of data published by anyone is insufficient on which to base commercial calculations.

The only new construction initiated during the year was the plant of the American Metal Co. at Burgettstown near Pittsburgh, Pennsylvania. The plant is not yet ready for operation. It is reported that the New

Jersey Zinc Co. interests will in the near future start construction of a plant at Martins Ferry, Ohio.

The effect of the change of duty on the future of the zinc industry is complicated by many factors. There is no doubt that under normal trade conditions in this country and Mexico the present scale of duties on ores and metal would work to the advantage of the smelter. Figuring old and new schedules on the basis of a 40% ore and a normal recovery of 640 lb. of metal therefrom, yields the following:

| | |
|---|--------|
| Old duty 1c. per lb. on zinc in ore..... | \$8.00 |
| Old duty 1 3/4 c. per lb. on metal imported 640 lb..... | 8.80 |

| | |
|---|--------|
| Protection for smelter per ton ore | \$0.80 |
| New duty 10% of \$14 for 40% at border | \$1.40 |
| New duty 15% on metal imported, value 4 1/4 c. London, 640 lb. | 4.10 |

| | |
|--|--------|
| Protection for smelter per ton ore when metal is 4 1/4 c. in Europe, 5c. in St. Louis' | \$2.70 |
|--|--------|

This makes a fair showing for the smelter, and one perhaps hardly intended by the tariff makers, but for the ore producer of the future the outlook is not so encouraging. When during the making of the Payne tariff bill, prayers were offered in the churches of Joplin for an extra heavy duty on ore, some profane Democrats were observed to scoff, but the tariff was certainly put high enough to satisfy any reasonable ore producer. Parties change and methods of making tariffs with them, but I am quite sure that the zinc ore producers and all good Republicans will agree with me that it is self evident that Mr. Underwood did not get his inspiration for the zinc ore tariff from the same source as did Mr. Payne.

Gold and Tin Dredging in 1913

By CHARLES JANIN

The gold dredging industry has had a quiet year; there has been no decided advance in methods employed, and few new dredges have been built, though a number of investigations of supposed dredging areas were carried on in different parts of the world. There has, on the other hand, been a decrease in the total number of dredges operating as compared to 1912 and the outlook in known dredging fields is not particularly bright for the future excepting perhaps in the far north and some in South American countries. In the Yukon the new 16-ft. dredge of the Canadian Klondyke Co., built by the Marion Steam Shovel Co., commenced operations and the four dredges of that Company are estimated to have made a profit over operating expenses of approximately \$750,000 for 1913. The North West Corporation was formed during the year to acquire A. N. C. Treadgold's holdings in the Granville Company and other claims and some new dredges will probably be ordered in 1914. The Granville is the holding company controlling 75% of the North West Corporation and 50% of the Canadian Klondyke Mining Company. The Yukon Gold Co. has dismantled two dredges which were operating near Dawson, and will move the machinery to the Iditarod. A small dredge ordered for unprospected ground in the Kotzebue district, Seward Peninsula, has also been sent to the Iditarod to be constructed next year.

In the Seward Peninsula the dredges in general have not had a successful year, the scarcity of water during the year and an early freeze up made a short season for most of the boats. Some areas, on which boats were built last year following the too frequent Alaskan practice of building a dredge before prospecting the ground, were found to have an insufficient gold content to pay operating expenses. Other dredges encountered difficult operating conditions, such as frozen ground, large boulders, etc., which had not been clearly defined or realized before. A few dredges, mostly of the flume type, and some in the Council district were operated successfully. There is a future for the flume type of dredge in Alaska and elsewhere if it is first properly determined that conditions are suitable for dredging and that there is a sufficient gold content to make the enterprise a financial success. Dredges cannot be moved as easily as chessmen and some idea of the gold content and working conditions to be encountered should be known before building a dredge, even an inexpensive one, on the haphazard chance that the ground might prove good. In other words prospecting with a dredge is neither good engineering nor good business.

It is said that the investigations of the Canadian Klondyke Co. on the Yukon have shown that after stripping the vegetation and top soil the underlying frozen gravel will be thawed sufficiently by the sun to permit of dredging without thawing by steam points as

practised by the Yukon Gold Co., thus permitting a much lower operating cost. This method of stripping and sun thawing I believe did not prove satisfactory when tried by the Yukon Gold Co., except in its first experiments. In actual practice it was found that steam thawing was necessary and during 1912 about 73.5% of the ground handled by the Yukon Gold Co.'s dredges near Dawson had to be thawed; the thawing cost accounts for about half the cost of operations.

Several extensive examinations were carried on in Russia and Siberia, but from what information I have, with the exception of a dredge for the Bodaibo district, all of these investigations of supposed dredging ground resulted unfavorably. It would seem that there is a field in Siberia and in Russia for small dredges of the flume type as used in Alaska if owners of some of the properties in question could be dealt with on a sane basis, and I believe that some of the dredges will undoubtedly be tried in the future.

The Pokrovsky dredge of the Orsk company, which was remodeled from the stacker scow formerly operated, started work during the year and reports a large increase in yardage as compared to the former methods. During 1912 the Kolchan dredge handled 382,550 yd. with an average recovery of 32.5 cents. The total operating costs of the dredge figured from the annual report of the Company are approximately as follows:

COST ON KOLCHAN DREDGE, 1912

| | Cents per cu. yd. |
|--|----------------------|
| Operating | 4.09 |
| Power plant | 3.8 |
| Winter up-keep | 2.37 |
| Administration (management, etc.) | 8.37 |
| | <hr/> 18.63 |
| Royalty | 6.3 |
| Depreciation, London and general expenses, interest, etc., | 10.4 |
| | <hr/> 35.33 |

To obtain the figures of royalty, depreciation, etc., I have divided the totals as shown in the report by the total yardage handled. The yield of gold for August, 1913, from both dredges is given at £10,343 and the total yardage as 116,000 as against 62,000 in July and 41,600 in June. This indicates the efficiency of the Pokrovsky dredge. The next annual report of the Company will be awaited with interest as a real profit over expenses is looked for.

In South America investigations were carried on in Peru, Brazil, British Guiana, and Colombia. In the first two countries examinations resulted unfavorably. In British Guiana a new dredge is to be built by the Minnehaha company already operating one dredge on the Potero river, also the Guiana Dredging Co. on the Konowarook reports a successful year and another 10%

dividend making 62% since the Company started operating in 1907. It is stated that this Company handles ground at a cost of 10c. per yard but as no figures of yardage are given in the annual report this is probably an estimation only. In Colombia a number of investigations were carried on, one with considerable preliminary advertisement but so far no new dredging areas have been found and no new gold dredges have been ordered. Considerable prospecting work will be done in Colombia during 1914 by the Pato, Oroville, and other interests. The investigations of the American Goldfields Development Co. to the south of the San Juan river on the west coast have resulted in a dredge being ordered for 1914 to recover the platinum and gold shown by prospecting.

Fraser & Chalmers is building a 5-ft. open-connected dredge for the Servia and if the results prove as anticipated other dredges will probably be built in the same field.

In the Far East

In the Philippines the results from Guamos dredge during the first four months of the year gave considerable satisfaction to the shareholders and other dredging men interested in the country. The latest reports, however, are that the ground proved deeper than expected, and that the digging ladder could not reach bedrock and consequently there was a considerable falling off in output. This caused a small panic among the shareholders. Late papers from the Islands talk of an investigation. It seems, however, that an extension on the digging ladder would be more to the point. I have been informed by the New York Engineering Co. which built this dredge that an extension to the digging ladder, was contemplated at the time of construction, to be put on when necessary. The 5-ft. dredge being built by the Yuba Construction Co. for the Philippines is fast nearing completion, and will be operating in December. The dredge for the Andrada Company in Portuguese East Africa was expected to be finished in November. This being built by the Bucyrus Company, under charge of T. C. Nicolson.

In West Africa the Offin River Gold Estates, which was formed in 1900 to acquire dredging rights on the Offin river, has had a continuous production of gold since 1904 but no profit is yet available to shareholders. The bullion recovered to the end of 1912 has been £186,003, about all of which has been swallowed by expenses. The Ashanti dredges are working under tributers, the operations of the Company being unsuccessful and unfavorable news is reported from the Ancobra dredging operations. Dredging in Africa has not been a success, due partly to building dredges unsuited to conditions of operations but mostly to poor advice when commencing operations. Had dredges properly designed to meet working conditions been built when the companies first started, and in some cases been properly handled afterward, a different tale might have been told to the shareholders.

Dredging in Spain has proved a failure and work has

been suspended pending a search for the 'pay channel,' which should have been done a little earlier. From Alaska to Spain is quite a leap but the same methods seem occasionally to be followed in both these countries as well as in others.

Some rich gravel is reported to have been found in San Domingo and if the values can be confirmed a new dredging area will be open to exploitation.

In the United States little of interest has occurred in dredging. There has been little new work in California, a number of boats have exhausted their holdings and one has been moved to other areas. One new dredge is reported, that of the Yukon Gold Co. near Auburn, the machinery of which was taken from an Oroville dredge which had been shut down. The Yuba Gold Fields had a successful year during 1912 and operations for 1913 are on the same order. The big all steel 14-cu. ft. dredge commenced work late in the year. The Natomas company has also had a fair year in its dredging operations and has overhauled several of its dredges. A new dredge was built by the Yuba Consolidated Co. for the Pabst interests near Salmon, Idaho, and the big 15-ft. dredge built by the same Company near Idaho City has been doing excellent work. A new dredge is reported for Gunnison county, Colorado. In Oregon the Powder River dredge is said to have done well and it is reported that a 3-ft. dredge has been ordered by the Gold Center Dredging Co., about 8 miles from Sumpter, Baker county.

Tin Dredging

While gold dredging has not shown much activity there has been a rapid progress in tin dredging operations and no review of dredging would be complete without some reference to the work done and the success made by the tin dredges. That tin dredging is widespread is learned by operations in the Malayan Peninsula the chief field for tin production, Nigeria where two dredges have been built during 1913, Alaska where the York dredge has been operating for three seasons, and in Portugal where a new dredge is being built which will commence operations in 1914. Among the companies which have ordered new dredges the Renong company in the Siam Eastern states operating one Werf Conrad dredge has ordered two more; the Tongkah Harbour Dredging Co. operating five Simon dredges has ordered a sixth; the Siamese Tin Dredging Co. has two new 14-cu. ft. Lobnitz dredges designed by Cutten Bros.; Fraser & Chalmers is building one for the Kamuning company in the Malay States; Arthur Brown is building two designed by Payne & Co. for the Malayan Tin Dredging Co.; two Werf Conrad dredges were sent to Nigeria; and Fraser & Chalmers has shipped a dredge which is being erected near Belmonte, Portugal. This latter is of interest as it is the first dredge of strictly California type to be built for tin dredging in Europe. It will have a close-connected bucket line of 4-ft. buckets, a steel hull, and will have a horizontal belt conveyor and be operated on spuds. The machinery will be driven by electricity. The boat

was designed by H. C. Peake of the Union Construction Co. for E. J. De Sabla.

The pump dredge has been successfully used for tin in the Malayan States and elsewhere and for a time two of these plants were operated in Cornwall. The high operating cost militates against their being adopted on areas suitable for dredging, or on areas unsuitable for dredging but having a low tin content. In Cornwall the cost averaged from 24 to 30c. per yard, and in the Malayan States according to Alexander Colledge* about 25c. per cu. yd. Though under extremely favorable conditions he figured it should be

done for 12c. Costs of tin dredging like costs of gold dredging, are sometimes a matter of book-keeping, and sometimes due to an overestimation of the yardage handled. The man with the most vivid imagination can thus obtain the lowest operating cost per cubic yard. In the Malay Peninsula it is generally accepted that dredging costs average from 9 to 10c. per yard. I have statements of costs under these figures but it is not stated how yardage is measured. For myself I prefer to figure on a basis of 10c. though a company operating a number of dredges under favorable conditions should do better than that.†

Recent Changes in Iron and Steel Manufacture

By BRADLEY STOUGHTON

Electric Smelting

There is but little recent advance of an industrial nature in the electric processes, and this applies especially to the electric smelting of iron ore, which does not seem to progress as rapidly as the advocates of the process and the theoretical calculations would lead us to expect. The electric steel furnaces, however, have increased rapidly in number. There are now nineteen in the United States, and commercial success seems to follow where electricity can be obtained at a low price. A number of improvements of minor nature have been made in steel-casting plants, and several new furnaces have been developed without any one of them coming specially to the front. The principal use of electricity in the manufacture of steel is in super-refining the product of the open-hearth or Bessemer furnace. The melting of scrap is also successful where electricity can be procured at a very low price, and where a good price can be obtained for castings of unusual quality. The melting of alloys to be used in open-hearth furnaces is also a successful electrical process, because of the possibility of melting without oxidation and waste of the costly alloys, such as manganese, chromium, etc. The refining of pig iron to steel is a process too costly to be generally applied on an industrial scale, but the melting of pig iron in the electric furnace for the manufacture of iron castings is said to be highly successful from the standpoint of the quality of the product. A new patented refractory material, consisting of boron nitride, will have important usefulness in electric furnaces if the claims of its inventor as to its fusibility and chemical inertness are borne out by practice.

Furnace Changes

A new furnace, having some of the characteristics of an electric furnace, a Bessemer converter and an open-hearth furnace, has been put in operation in Maryland, but has not been tried long enough to prove the industrial value of the apparatus. The Stock oil-fired

converter is a combination of the ordinary sideblow steel-casting converter and the reverberatory oil furnace for melting iron.

There is a tendency at the present time to return to the tilting type of open-hearth furnace as compared with the stationary type, on the ground of greater convenience, notwithstanding the heavy cost of repairs because of the strain in the brick-work during the tilting. A recent development in the heating of open-hearth furnaces is the use of blast-furnace gas mixed with coke oven gas. A process with future industrial possibilities involves the following principles: By means of carbon monoxide gas it is possible almost completely to reduce iron ore and produce a somewhat impure form of iron sponge, without the use of a blast-furnace, the resulting iron sponge can be melted and purified in the open-hearth furnace and thus produce steel from iron ore in a two-step process similar to the prevailing commercial process for steel manufacture, except that it is not necessary to use coke or other solid fuel.

The Roe mechanical puddling furnace, which was developed several years ago, is being tried on an industrial scale and apparently with satisfaction to its users.

Fuel Problems

The industrial use of oxygen for enriching the blast driven into the iron blast-furnace has been increasing so fast, and the price of oxygen is so much reduced, that it would seem to offer important possibilities to metallurgists interested in pyritic smelting of copper ores and the bessemerizing of copper, because of the valuable possibilities for abundantly and rapidly increasing the temperature of the operation without at the same time endangering the reduction of iron.

The increase in the price of fuel oil in the eastern part of the United States has caused a great extension in the use of pulverized coal for heating, melting, and annealing. The use of pulverized coal enables the

*The Mining Magazine, July, 1913.

†A further review by states and districts will be printed later.

engineer to control with great accuracy and facility the temperature and the composition of the flame; it gives a higher temperature than can be obtained with oil, and avoids the difficulty of deposition of graphite and soot, without at the same time requiring preheated air or too oxidizing an atmosphere in the furnace. Pulverized coal has, however, the disadvantage of being very severe upon the brickwork of the furnace, although much progress has recently been made in this respect.

Recent investigations into the heat lost from cupolas have shown the possibility of melting iron with a smaller proportion of coke than has been customary. A process has been announced for desulphurizing iron by blowing air through the bath of the liquid metal in such a way as to cause the manganese sulphide to rise to the surface, but without oxidizing the silicon and carbon and without increasing the temperature of the metal, as is done in the blowing of the ordinary Bessemer process. Steel borings and turnings have been melted in the cupola, without the ordinary briquetting or the canning processes, by blowing the fine particles in through the tuyeres with the blast. A process has also been announced from Sweden for the dephosphorization of iron by oxidation with air at a low temperature. The details of its commercial possibilities are not yet known.

Research in Steel and Iron

The tremendous industrial importance of the critical points of steel for all those interested in annealing or tempering steel is now well recognized. During 1913 a new method has been developed for the determination of the A_1 and A_2 points, and progress has been made in the elucidation of the mysterious hardness of steel by researches upon the properties of the allotropic modifications of iron.

A very important investigation by J. E. Johnson, Jr., was published in 1913 upon the 'Effect of Carbon on the Quality of Cast Iron,' which proved the special influence of the eutectic ratio upon the properties of this metal.

One of the most notable advances of the year has been the increased attention given to the ingot-forming stage of the steel-making processes, and the steps that are now being taken for insuring the production of sound ingots. Perhaps the greatest of all these steps has been the very efficient method of supervision of the process of manufacture, which is carried on and recorded by inspectors acting on behalf of the purchaser in the works of the manufacturer. Several important processes for the elimination of pipes from the ingots, by causing the upper portion to cool more slowly than the lower and thus draw the shrinkage cavity nearer the top of the ingot, have been described and introduced.

The diffusion of hydrogen gas through steel at a high temperature has resulted in the removal of some sulphur, phosphorous, and carbon in the form of hydrides without any harmful absorption of the hydrogen by the metal. An interesting study of the limit of the amount of oxygen absorbed by molten iron disclosed the wholly unexpected result that not more than

0.074% could be absorbed. The harmful influence of oxygen on iron and steel has made a good, rapid method for the determination of this element of great value. Much research has been carried on during 1913 to this end, and although full success cannot yet be claimed, the end is nearer than ever before. Progress has also been made in the development of a rapid method for the determination of nitrogen in steel, and evidence has been obtained which further indicates the harmful effect of this element on the quality of the metal. This has long been a disputed question.

Alloy Steels

Manganese steel, which is very extensively used for parts of crushing machinery and other apparatus which is subjected to great wear, is now commonly forged both hot and cold. It has recently been shown that it can be made either non-magnetic or magnetic, and that it has the great peculiarity of exhibiting changes in structure that do not seem to be related to critical points in its heating and cooling curves. Mayari cast iron and Mayari steel are natural alloys of iron, nickel, and chromium which can be made from some of the ores of Cuba and some of the ores of Greece without the addition of any alloying materials. They possess greater strength, hardness and durability than does ordinary iron and steel without the nickel and chromium, and are coming into extensive use in engineering. Cobalt is one of the latest additions to steel and is said to give greatly increased durability, especially in high-speed steels. Copper steel, containing from 0.1 to 0.5% copper, has been experimented with by many investigators in recent years in their search for a material which will give extra resistance to corrosion and durability against wear, such as is needed for railroad rails, for example.

Iron Ore Deposits

The iron ore deposits of Texas, Mexico, Central and South America have been developed to a very great extent and have attracted much attention in recent years. One of the largest of the eastern steel plants has acquired great holdings in Chile, and arrangements are being perfected for marketing Brazilian ores on a large scale. The opening of the Panama canal will, no doubt, bring the great deposits known to exist south of the Equator into still further prominence.

Colorado mines produced in the eleven months of 1913, with an estimate for December, according to Charles W. Henderson, of the U. S. Geological Survey, \$18,395,000 in gold, 9,150,000 oz. of silver, 85,500,000 lb. of lead, 7,634,000 lb. of copper, and 129,680,000 lb. of zinc, with a total value of \$36,200,000, compared with \$37,320,996 in 1912. This shows a decrease of \$200,000 in gold, an increase of 900,000 oz. of silver, an increase of 10,300,000 lb. of lead, an increase of 500,000 lb. of copper, and a decrease of 2,540,000 lb. of zinc. The heaviest decrease in value was \$1,732,000 for zinc, and there were increases of \$440,000 for silver and \$377,000 for lead.

FIG. 1. SURFACE WORKINGS AT MOUNT LYELL, TASMANIA.

Mining Methods and Practice

By E. H. LESLIE

Reviewing this broad subject in the fewest possible words, it may be said that the effort is everywhere to reduce costs by increasing the scale of operations. Results on the Rand, where large capital expenditure has been called for, have not been altogether happy, but in general the movement is making possible the working of deposits lower and lower in grade. Lake Superior mines have pointed the way in open-pit work and in caving methods, and central electric stations are everywhere reducing power costs. Gas and oil-engines are making constant inroads on the field of steam, but the time-honored Corliss is still far from being driven from the field. Improved efficiency is being sought in every department. In underground work the one-man stoping drill has come to stay. In the Lake Superior copper mines it has reduced the stoping cost from 50 to 15 cents and increased the tonnage broken from 12 to 30. The motorman is replacing the 'mule-skinner'; crushing and sorting underground is finding favor; use of conveyor belts is increasing; grouting systems for reducing pumping charges are coming to be recognized; loading machines are being tried; and there is a distinct tendency toward making repairs to drills and pumps, and conducting drill sharpening, crushing, and sorting underground. The chief difficulty in the latter has been the outlay for separate equipment on each level, but by centring the work this is being met. Ventilation, of course, must be provided, but this is not proving difficult in practice. The efficiency of drills has been much studied at the North Star in California during the past year, and a rock-drill testing machine,¹ which gives promise of great savings, has been invented. Underground ore-crushing is now past the experimental stage and has been found to be espe-

cially advantageous where 'bulldozing' and underground sorting are necessary. The jaw-crusher recently installed on the 14th level of the Witwatersrand Gold Mining Co.'s property is used to crush the large rocks formerly broken by hand, and the discharge from crusher is sent direct to the shaft bins. At the Round Mountain Mining Co.'s property in Nevada during the year one underground crusher broke 22,688 tons of ore, of which 16,306 tons was rejected as waste and left underground, and another crushed 56,188 tons, of which 40,589 tons was rejected. The cost of mining this material is from \$0.80 to \$1 per ton, while the crushing, screening, and transportation, including all repairs and renewals, amounted to from 5 to 6c. per ton. The often advanced objection, the supposed bad effect upon the mine atmosphere, is not borne out in practice. At the Knight property on the Rand the crusher station is surrounded with atomizers and the amount of dust created is exceedingly small.

Mining Machines

The application of mining machines to metal mines is one of the latest developments. In the mining of coal, which, by the way, forms a subject worthy of the attention of the metal miner, mining machines have made possible the immense tonnages and rapid development which is characteristic of that industry. Recently they have been introduced on the Mesabi iron range,² where the influx of miners has not kept pace with the demand for increased output. At the Harold mine, in the Hibbing district, a pick machine is being successfully used in soft ground. Under the old method the miners drilled a round of 3 to 5 holes in the breast, each hole about 5 ft. in depth. The upper holes were usually fired first and the bottom

¹'Rock-Drill Testing at the North Star,' by Robert H. Bedford and William Hague, *Mining and Scientific Press*, August 2, 1913.

²H. E. Martin and W. H. Kaiser, *Trans. Lake Superior Mining Institute*.

holes after the broken ground had been removed. The amount of dynamite depended upon conditions, and varied from $7\frac{1}{2}$ to 15 lb. After the upper holes were fired the miners secured the back by poling from the last set of timber into the breast. When the broken ore had been removed, the miners trimmed the breast, back, and sides, and the ground was ready for timber. When doing the work with machines, the number of men required per crew is 2 machine men, 3 miners, and 6 shovelers. The minimum number of working places or rooms required for one machine has been found to be five, though a larger number will insure fewer delays and make for higher efficiency. The log of one round of operations is as follows: The ground is first undercut with the puncher to a depth of about five feet, the cut extending from the solid rib to within six inches or so of the opposite side, thus leaving a small pillar six inches wide and the full length of the 'set'; the object in leaving the pillar being to prevent premature caving. Two holes are then drilled with the air augur about one foot from the solid rib and spaced about two and six feet, respectively, from the back. Sometimes four holes are necessary. Two short holes are drilled in the small pillar supporting the ground, shoveling boards are placed in the cut, and under the ground to be broken, and the holes are loaded and fired. The back is then secured with poles and the room is ready to be cleaned. After the broken ore has been removed, the miners spare up the set, place the timber, and another cycle of operation is started. The average time for under-cutting one block of ground is 59 minutes, moving and setting the machine 26 minutes, drilling with the air augur 2.8 minutes per foot.

Aside from reducing the cost of production, the machine requires but one-half of the labor to be skilled miners, only one-half the amount of dynamite is required, there is less liability of the posts being blasted out, and there is always a smooth surface from which to shovel. The rooms worked by machine must be easy of access from one to another. Their height should not be less than seven or eight feet, and no bottom stoping should be necessary. In other words, the machines are applicable to slicing and square-set methods. While the mining conditions have not been ideal for the use of the machine, after five weeks' trial it was found that the average number of tons per man was 12, which is considerably above the average in most of the underground mines on the Mesabi. From the results obtained it is evident that the machines have found a place in iron mining.

Mining Methods at Joplin

At the present time over 50% of the concentrate produced in the Joplin district is from 'sheet ground' properties, that being a local name for a blanket deposit. The blanket from which the bulk of the output of the district is obtained varies from 8 to 20 ft. in thickness and lies at a depth of from 100 to 200 ft. As a rule, the ore-bearing ground lies under

a heavy limestone, which is supported by pillars of from 20 to 40 ft. in diameter, about 50 ft. apart. The ore occurs in a formation known as the Grand Falls chert, which is extremely hard, and is broken with air-drills and 40% dynamite by underhand stoping. The ore is shoveled from the faces of the stopes into tubs and run to the circular shaft on low platform cars. Another type of deposit is known as hard disseminated ground. In these deposits a good back is usually had and the mining is practically the same as in sheet ground with the exception that rooms are often cut out 30 to 40 ft. wide, 50 to 150 ft. long, and 20 to 100 ft. high. The third class of deposit is that which is known as 'soft' ground. In this form of deposit the roof is supported by timbers. The usual method of timbering consists of a cap and posts with collar braces, each set being tied to the one behind. It often happens that spiling boards are necessary, and lagging is used on the sides of the drifts. The average cost of mining in this district for all types of mines including sheet and soft ground is about \$1 per ton. This cost does not include amortization. Methods of mining in the Joplin district have been briefly described within the year by Clarence A. Wright in one of the series of technical papers published by the U. S. Bureau of Mines.

Flat River

The methods of mining used in the lead belt of southeastern Missouri are similar in some particulars to those at Joplin, underhand stoping and pillars being used. Operations in general, however, are on a much larger scale, and the equipment is of a more permanent nature. Prospecting is done largely by diamond-drills in the Flat River district, and mules and electricity are employed for underground tramming. The subject has been fully treated recently by H. A. Guess³ in a most interesting and valuable paper.

In both districts the pumping charge constitutes one of the big items of expense, and it seems probable that larger use could be made of the method of plugging water channels. The combination of wedging and grouting introduced by E. B. Kirby at the Federal Lead Co.'s property at Flat River, some years ago, proved a simple and efficient method of sealing and saved a large amount of pumping. By this method the channel is stopped with wooden or iron wedges, a pipe being first inserted into the channel through which the grouting is pumped. Pumping operations are continued until the flow of water from the channel has ceased, when the pipe is capped and the operation is completed. For filling the channel, either clay, sawdust, or a fine concrete may be used. When earth is used, a settling device in the form of a three-compartment classifier is employed. Only the finer material, that collected in the last compartment, is used for grouting purposes. George S. Rice has called at-

³'Mining and Mining Methods in the Southeast Missouri Disseminated-Lead District,' H. A. Guess, *Trans. Amer. Inst. Min. Eng.*, December 1913.

tention⁴ to an application of the method to preventing rock slides, and Francis Donaldson⁵ has discussed the matter in connection with shaft-sinking.

Square-Set Stopping

The square-set method of stopping, which was the standard practice for a number of years, has become modified and a combination with the filling system is being widely adopted. The Snow-Storm property at Larson, Idaho, presents an example of square-set and fill system. At this property the vein outcrops near the top of the mountain and dips at an angle of 65°. It is opened by four cross-cut adits at depths of 100, 200, 1100, and 1600 ft. vertically below the outcrop. Mining at present is being conducted through the 1100-ft. adit, which is about 1800 ft. long. The adits are connected by raises in the vein and drifts are made in the ore at approximately 100-ft. intervals. The stopes extend from one level to the level above. A back is left beneath each level until the ore is mined. The stopes are filled with waste material obtained from underground sorting and an open-cut. The sets are 6 ft. square and 8 ft. high. A plank ore-chute, timber chute, and man-way are carried up about every fifth set. Temporary incline chutes are put in when necessary. The ore is trammed by hand on the levels and dropped through rock raises to the adit-level, where it is trammed by horses to the portal of the adit and thence by aerial tramway to the mill at Larson. Ingersoll-Rand 3¼ and 3⅝-in. piston drills are used for driving, Waugh hammer-drills for raises and stopes, and Ingersoll-Rand jack-hammer drills for sinking. The cost of production for the year ended July 1, 1913, was \$1.444 for shipping ore and \$1.474 for milling ore.

At Victor and Cripple Creek the general method of mining is by stilled stopes, varied occasionally by filled stopes, or where the shoot is wide, by square sets. Stopping drills of the Leyner, Shaw, and Waugh makes are used for all general work, and with the aid of the 'blow-pipe' a great deal of driving and cross-cutting is done with these light drills. The machines generally used for long drifts are the Ingersoll 2¼-in. and the Leyner piston machines. At Stratton's Independence driving on a small vein in granite with 2¼-in. machine cost \$4.44 per foot, while the stoper in phonolite and porphyry the cost was \$3.25 per foot. Ordinary raising with a stoper is being done at a cost of \$3.50 per foot, while raising in caved ground averages \$9.19 per foot. The Independence property caved from the surface to the 500-ft. level in 1907 since which time a large part of the work has been in broken ground. The average cost of driving and cross-cutting in 1913 was \$4.10 per foot, while for development the cost averaged \$4.65 per foot of advance, covering all kinds of ground, both caved and solid. There is but one man to a machine, even on the Leyner and 2¼-in. machines, though a shoveler is allowed to help set up.

In the mining of wide lodes it has become customary to provide permanent tramming drifts in the foot-wall. From these, cross-cuts are driven through the orebody, from which stopping operations are conducted. As an example of this class of mining, the method at the South mine at Kalgoorlie may be cited.⁶ It is known as the 'rill floor' method and various adaptations of it are in vogue in the mines of Broken Hill. It provides for filling while the stopes are being worked.

At the property of the Mount Lyell Mining & Railway Co., at Mount Lyell, Tasmania, a similar method of mining has been adopted, which is a combination of surface and underground methods, and also bears some resemblance to the milling system of the Lake Superior district. Fig. 1 shows the surface workings, from which the idea of the scope and method of mining operations may be had. At the present time work is being continued on the overburden and ore benches, and a large tonnage is being uncovered. All of the filling for the underground workings is obtained from this source. As the property develops, the tendency is toward a diminution in the tonnage mined from the surface and an increase in the tonnage from underground workings, as at the Treadwell in Alaska.

The pit is worked in benches with air-drills and cars, the ore being either trammed from the benches through a tunnel to bins on the mountain slope, or dropped by gravity to the underground workings and thence to the surface. At the present rate of mining there is being stoped from the open pit of the Mount Lyell mine about 650 tons per day. The properties altogether produce about 30,000 tons per month at a cost of about \$2.25 per ton.

Caving Methods

Slicing and caving methods have been developed in the underground mining of Lake Superior iron ores to an extent not equaled elsewhere. For the first time these methods were comprehensively described within the year, in a volume⁷ written by C. E. van Barneveld and published by the University of Minnesota. By these methods the development period is made shorter than when open-pit methods are used, and the preliminary work, as a rule, is much cheaper. Another advantage of the caving system is that it is possible to select the ore and maintain more uniform grades than in open-pit and steam-shovel mining, as the unit of operation is smaller. The capital outlay for equipment is much less, and the method requires but a comparatively small amount of timber. The extraction is also high, being estimated at from 95 to 98 per cent.

The many advantages of these methods are leading to their wide introduction in the copper-mining districts of the West where wholesale mining is in vogue. At the Miami mine, near Globe, Arizona, a shrinkage method is employed which has made possible a cost of

⁴Jour. Wes. Soc. Eng., September 1913.

\$1.20 per ton. An interesting recent development is the handling of ore from the dump by means of a special form of drag-bucket scraper, described within the year.⁸ The drag-bucket, by the way, is now extensively used in mining iron ore in Cuba, and has found many applications in placer mining. At the Inspiration mine the method used underground is similar to that at Miami, though haulage is by means of compressed air and there are other differences. At Ray, the general system has been materially modified, and, as representing the latest development, may be described. The Ray orebody as developed by churn-drills is reputed to be the second largest in the world. The ore is in the shape of a huge blanket deposit with an average thickness of 107 ft. over an area of 183 acres. A detailed account of the mining of this orebody has

drifts are timbered with 12 by 12-in. timber sets on 5-ft. centres. On top of these drift sets, which lie within the orebody at intervals of 25 ft., 'pony sets' are erected to hold the stope chutes, and midway between the stope chutes are erected 'pony sets' for holding the pillar chutes.

While the haulage-way drifts are being driven, smaller manway drifts are progressing at 100-ft. intervals on the sub-level 25 or 30 ft. above. These manway drifts are offset 12½ ft. to one side of the motor drifts, and out of them are run at right angles a series of parallel sub-drifts placed every 25 ft. over the whole orebody. These are driven so as to be directly over the stope chutes on the motor level, so that when raises are made from the stope chutes they will break into the stope drifts and become chutes

FIG. 2. LONGITUDINAL SECTION.

FIG. 3. CROSS-SECTION, SHRINKAGE STOPES AND PILLARS.

recently been written by L. A. Blackner,⁹ an abstract of which is reproduced here through his courtesy.

Owing to the heavy overburden and the low grade of the ore, it is necessary that a large tonnage be produced per day, and toward this end a caving system has been developed, which consists of weakening a block of ore by a series of shrinkage stopes, when, after undermining pillars, the ore is drawn down systematically, the capping crushing and settling gradually over it. At the present ore is being mined from two shafts by this method, while a third, in high-grade ore, opens a body which is mined by square-set methods. The low-grade deposits are opened by three motor-haulage levels. On each motor level a main drift is driven from the hoisting shaft along the edge of the orebody; from this drift a series of parallel side-drifts are run at 50-ft. intervals and completely through the orebody to a 'fringe drift' which runs parallel to the main drift. Somewhere at a convenient place along the main drift and outside of the orebody there is put in a raise to the sub-levels, as shown in Fig. 2 and Fig. 3. This raise is usually divided into two compartments, one to be used as a manway and the other for hoisting tools and supplies. The parallel

through which the ore is drawn to the tramming level. On a second sub-level, which is placed about 100 ft. above the first, manway drifts are driven parallel and directly above those on the first sub-level. These later serve as passageways through which the men and supplies enter and leave the stopes, and they also serve for ventilation. Along the manways of the first sub-level at intervals of 25 ft., or 7½ ft. from the centre of each stope, there are put in manway raises to the drifts on the second sub-level. Chain ladders are used in these raises for the use of the men. While the manway raises are being put in, men with stoper machines 'bell out' the chute raises so that when finished they have the appearance of funnels or inverted bells. In starting a stope, men with stopers drill a line of holes into the side of the stope drift. This line of holes, when blasted together, widens the drifts to 15 ft., so that they are ready to be mined and stoping operations commenced.

When this has been completed, manway sets of 8 by 8-in. timber are erected in the manway drifts. In mining a stope, two lines of holes are drilled with stoper machines all along the back on both sides of the stope, one line near the side walls with the holes slightly 'toeing' toward them, the other about four feet away, with the holes inclined slightly toward the centre of

⁸Mining and Scientific Press, November 1, 1913.

⁹The Ray System of Mining Ore, Arizona Copper Camp.

the stope. In hard ground it is sometimes necessary to put in a third set of holes. The holes are loaded with three or four sticks of 40% dynamite and 7-ft. fuses are used. The ore is drawn from the stope chutes into 5-ton cars on the motor level and trammed to the shaft. Only enough ore is drawn from the stopes to allow the miners head room in drilling. Air for the machines is supplied through a supply hose dropped from the second sub-level. The manways are always built up above the broken ore, so as to keep them clear. When the stope has reached a point midway between the first and second sub-levels, the men usually descend into the stope through the manway raises, and the cribbed manways are left behind.

the ore. The total cost of mining by this method for the past year, including crushing the ore through an inch-mesh screen and delivering it on board cars with a proper apportionment of all fixed charges, was 77.55c. per ton. This cost is higher than the costs applying to those parts of the mine which have been sufficiently opened to permit of economical working, and is accordingly higher than it will be in the future.

Steam-Shovel Operations

Steam-shovel operation as applied to mining may well be said to be the most important development which the mining industry of the later day has experienced. The economic conduct of the operations, although seem-

FIG. 5. STEAM-SHOVEL WORK AT BINGHAM, UTAH.

When a block of ore has been mined by a series of such stopes, the undermining of the pillars is commenced, starting with the pillar nearest the 'fringe drift' on the motor level. Raises are run out on inclines from each pillar chute until they intersect. From these raises at a distance of 10 or 12 ft. from the chutes, raises are run back so as to connect with each other directly over the motor drifts. After the raises have been connected all along the pillar, they are widened and drilled and blasted with deep holes, so as to undercut the entire pillar. Each consecutive pillar is mined in this manner.

In most cases the orebody and capping is badly shattered and broken so that when the pillars are undercut the capping breaks in a nearly perpendicular plane to the surface completely around the area. An accurate account is kept of the ore taken from every chute, so that the ore remaining in each is always known. Only a few cars are drawn from any one chute at a time, so as to give the ore time to settle gradually with the capping following after and without mixing with

ingly simple, presents problems which if not properly analyzed may result in the difference between a profitable and unprofitable investment. Thorough prospecting, efficient arrangement of the workings, and thorough organization are the main points for consideration in open-pit or steam-shovel mining. As typical of this class of mining, the iron ranges of Minnesota present the standard practice, which with modifications to meet local conditions, have made possible the so-called porphyry-copper mines of the West. Excellent work is being done at Bingham, Utah, Chino, New Mexico, and Ely, Nevada. Steam-shovels are also used in coal-mining in Kansas, Illinois, and other states, and in placer mining.

Prospecting, if thoroughly conducted with churn, diamond-drills, or augurs (as at Moa) will clearly define the nature of the deposit, position and extent of commercial ore, amount of stripping, laying out the pit, entrance and grades, and position of benches upon which all subsequent operations are based. Without going into detail, the importance of each step is ap-

parent and each has been fully discussed by various writers in the technical press. The shovel itself is the keystone of efficiency. The tendency, which has been toward the adoption of shovels of increasing size has been stopped, and the 100-ton shovel, or thereabouts, has come to be accepted as standard. The difficulty with the larger and more powerful machine lies in the increased wear and tear due to rough handling, which increases repair charges and decreases running time. In steam-shovel work it is important to make every arrangement with a view to securing full time work with the shovels.

The orebody being mined by the Utah Copper Co. consists of lenses of ore with rock capping on the sides of Bingham and Carr Fork cañons. Owing to the unfavorable position of the orebody on steep mountain-sides, the site is not the most favorable for steam-shovel operations. Stripping operations require the

and has an average thickness of about 220 ft. The ore consists of chalcopryite, chalcocite, and pyrite disseminated through a highly-altered porphyry, lying in great lenses at an average depth of 100 ft. below the surface. The deposit, being flat, is adapted to the same methods of mining as those employed in the Lake Superior iron pits. Stripping operations are conducted by steam-shovel at a cost of 33.64c. per cubic yard. In the stripping of this orebody, up to the beginning of last year, there has been removed 9,916,024 cu. yd. The longitudinal section, Fig. 6, through the deposit shows the amount of stripping necessary, the position of the orebody, the positions of the benches, and method of working. As the pit is widened and deepened, stripping and mining operations are carried on simultaneously. The difference in elevations of the benches is about 50 ft., and they are about 50 ft. wide. Operations are conducted by seven 95-ton and one 70-ton

FIG. 6. LONGITUDINAL SECTION THROUGH THE COPPER FLAT OREBODY.

removal of capping in the ratio of one of rock to between three and four of ore. The average thickness of the capping is 110 ft., the total amount removed last year being 4,676,568 cu. yd., and was removed at a cost, including prospecting, of 8.84c. per ton of ore produced. The position of the workings and the steam-shovel benches are as shown in Fig. 5. The benches are connected by switchbacks and are at about 75 ft. differences in elevation. The capping and ore are broken by giant blasts. 'T'-shaped gopher holes are sometimes driven into the bank and giant blasts of black powder, ignited by dynamite and electric fuse, are used. Churn-drill holes are the common practice, eleven churn-drills being employed for this purpose. The holes are of 6-in. diameter and spaced according to the ground, the holes having a burden of 35 to 40 ft. at the bottom. The stripped material is handled by dump-cars, while the ore is shoveled directly into standard gage ore-cars of 100,000-lb. capacity and taken to the mills. The 22 standard-gage steam-shovels operate about 60% of the time. The actual cost of mining by this method last year was 26.35c. per ton, to which must be added the stripping and prospecting charge of 8.84 cents.

The Copper Flat deposit of the Nevada Consolidated presents an excellent opportunity for steam-shovel working. There are three pits, the Eureka, Liberty, and Hecla. The deposit is 2600 ft. long and 1200 ft. wide,

and has an average thickness of about 220 ft. The ore consists of chalcopryite, chalcocite, and pyrite disseminated through a highly-altered porphyry, lying in great lenses at an average depth of 100 ft. below the surface. The deposit, being flat, is adapted to the same methods of mining as those employed in the Lake Superior iron pits. Stripping operations are conducted by steam-shovel at a cost of 33.64c. per cubic yard. In the stripping of this orebody, up to the beginning of last year, there has been removed 9,916,024 cu. yd. The longitudinal section, Fig. 6, through the deposit shows the amount of stripping necessary, the position of the orebody, the positions of the benches, and method of working. As the pit is widened and deepened, stripping and mining operations are carried on simultaneously. The difference in elevations of the benches is about 50 ft., and they are about 50 ft. wide. Operations are conducted by seven 95-ton and one 70-ton

steam-shovels. In blasting, 'T'-shaped gopher holes are driven into the bank, as at Bingham, and churn-drill holes are used. The churn-drill holes are of 6 in. diameter and from 50 to 100 ft. in depth. They are chambered before firing.¹⁰ The present method of moving the drill by a crane has been found to be a very decided improvement over the old method of making roads and moving it by its own power. Five men are required where formerly ten were necessary, and a great deal of time is saved. The actual cost of mining, including labor, supplies, repairs, management, taxes, etc., at the time of the last annual report, was 17.35c. per dry ton. During the last year of operations reported, there was mined by steam-shovel methods a total of 2,596,991 tons of ore averaging 1.603% copper.

In this review only those features of modern practice as applied to the more important types of lode deposits have been touched, in the hope that such a general survey of the subject may point out the trend of present-day methods and the possibilities of increased mining efficiency. While the step from breaking ore by heat to the stoper and dynamite, from the 'chicken' ladder of the Aztecs to the giant hoists of Lake Superior and Butte, from the divining rod to the diamond-drill, and from gopher methods to the steam-shovel has been a long one, there is still room for improvement.

The Decline of the Rand

By H. S. DENNY

There is something impressive in the suggestion that the huge gold-producing industry of the Rand has reached the downhill side of its wonderful career, and it smacks of the paradoxical to affirm this in the face of a record of steadily increasing gross production. Nevertheless, a study of the position must inevitably lead one to this conclusion, despite the fact that for the year 1912 the Witwatersrand produced gold to the enormous value of over £37,000,000 sterling, being an increase of over 3½ millions as compared with the previous year. The explanation, of course, is that as against the continued increase in production there is a marked decrease in the amount of distributable profit. The sum of dividends distributed shows a steady advance up to 1909, but the record since then, as indicated by the following summary—is eloquent of the change that has come over the industry:

| Year | Tons milled | Output | Dividends |
|------------------|-------------|-------------|-------------|
| 1909 | 20,543,759 | £29,900,359 | £9,523,518 |
| 1912 | 29,163,803 | 37,182,795 | 8,331,575 |
| Difference | +8,620,044 | +7,282,436 | =£1,191,940 |

Since 1909, therefore, the tonnage crushed has increased say 40% and the output 24%, while the dividends have decreased 12%. From the investor's, and in fact from almost any, standpoint, the vital figure is naturally the dividend, and since the capability of the industry to continue its life depends upon its concurrent capability to earn dividends, it may logically be argued that the serious droop in the latter direction may be safely regarded as an indication that its vitality is on the wane. Every effort has been made to keep on the up-grade, because it was realized that once a sign of serious falling off became visible, all hope of ever recovering would practically be gone. The brains and the energies of the administration have, therefore, been turned from one point to another until it may be said with certainty that all the obvious remedial expedients have had a trial. In the past ten years we have seen the adoption of:

The tube-mill, with increased stamp-duty and higher gold-recovery.

Heavy stamps, with lower capital outlay and greater unit-efficiency.

Hand-stopping in narrow stopes, with less waste rock and therefore higher-grade mill-ore.

Machine-stopping in wide stopes, saving hand-labor, and giving large tonnage at low cost.

Selective mining, to give the maximum possible profit in the shortest possible time.

Central power-plants, to reduce the cost of energy.

Central administration, to reduce management charges and to increase general efficiency.

And what has been the result of it all? Certainly largely increased capital outlay, and equally certainly

much greater tonnage of rock handled, and undoubtedly a reduced 'working cost' per ton, but unfortunately a lower yield per ton and a smaller profit per ton.

There has been great argument as to the relative merits of big tonnage and low-grade ore, as opposed to small tonnage and high-grade ore. The objection to the former policy is that it has entailed heavy capital outlay and that it has led to the milling of much worthless rock. It is claimed, moreover, that any advantage thus gained in operating cost has been more than offset by dilution of grade. Against these arguments it is contended that 'working costs' have been reduced with the result that lower-grade ores could be worked at a profit.

Limits of Wholesale Mining

Without a doubt the practice of increased tonnage at any cost has been carried, in some cases, too far. There is a critical point naturally in the relationship of the tonnage milled per day to the economic working of any mine, but in arriving at this point, due weight must be given to a number of contingent factors such as labor, number of shafts, development facilities, etc., and any one of these may in itself set a limit to the possibilities. That is to say, it might be figured that a property containing a probable billion tons of ore would appear to be unsuitably equipped if it had a plant of only 100 tons per day capacity, and certainly, on the basis of working out the mine in any reasonable 'life,' it would appear to be so; but, for the reasons bound up in the contingent factors, above indicated, it might be quite impossible *efficiently* to handle more than 100 tons per day. In such a case, an equipment of 200 tons capacity would probably lead to inefficient work in the attempt to keep that plant running full time, and the result would be disappointing from every aspect. Apparently this is what has happened in many instances on the Rand. Shortness of labor, coupled with other difficulties, has forced managers to resort to all forms of expedients for keeping their mills running—the commonest evil being the inclusion of waste-rock with the mill-ore. Waste not only costs just as much to crush and treat as ore, but whereas it contains nothing when it comes to the mill, it has actually carried with it some of the precious metal when it is finally dumped. It has, therefore, substantially swelled the monthly statement of working expenditure, and has simultaneously appreciably reduced the revenue—both very undesirable results. Personally I hold the opinion that it is largely for this reason that, in several instances on the Rand, the increase of milling capacity has been attended with unsatisfactory results, and the degree of the disappointment is only properly realized when allowance is made for the amortization

of the additional amounts of capital involved. Take, for instance, the case of a company crushing 300 tons per day for 320 days per annum with a 20 years' life. Assume it increases its capacity to 600 tons for an outlay of £120,000. Without charging any interest, this sum would represent in its redemption an amount of 1.3 shillings for every ton of ore milled during the rest of the life of the mine, and if a reasonable rate of compound interest be allowed it becomes a correspondingly more serious matter. Unless a mine is in a position adequately to satisfy the demand for the larger tonnage, therefore, without undue strain at any point, it cannot do it to advantage. Hoisting shafts, surface and underground ore-stations, stope-faces, tram-levels, breaker-stations, etc., are all called upon for extra duty, and it has not infrequently occurred that, while the treatment plant has had its capacity doubled, nothing has been done relatively to increase the capacity at other points, and the management immediately upon starting its new equipment, has found itself in serious trouble with no possibility of saving the situation except by shutting down—a resort too alarming from the stock market standpoint to be feasible. In shaft-work alone the additional time required for introducing and clearing the increased number of under-ground laborers, and handling the extra amount of tools, stores, etc., is in itself an important matter—especially in deep mines—that must be considered before the question of handling extra milling and development rock is solved.

Then again the demand for largely increased development area and number of stope-faces has in many cases not been properly met. In short, while every care has been bestowed upon the reduction plant, the tendency has been to neglect the more vital underground part, with the result already indicated.

A legitimate increase in milling capacity, consistent with the other features specified, must be beneficial to the business side of the profit-and-loss account, but it may easily be conceived from the foregoing remarks that an ill considered, or one-sided increase, might not only fail to secure any real benefit, but might even do great and lasting injury; and when this was done merely to follow out a fashion that had for its object the automatic lowering of working cost, there is no doubt that it was unprofitable.

Investors might therefore have been saved a large amount of capital outlay that indirectly has had to come from their pockets.

The Labor Shortage

The labor difficulty has been more serious than is realized by most people outside the Rand, and ever since the repatriation of the Chinese, there has been a shortage in the supply. It will be remembered that at the end of the Boer war, there was a great deal of optimism regarding the supply of native labor, and the leaders of the industry, men of great experience, were confident that with the declaration of peace would come a big inflow of natives. In this they were disap-

pointed. When it became clear that the supply was unequal to the demand, recourse was had to Chinese labor. The initial cost of the introduction of this labor was exceedingly heavy, first because of the stringent regulations in regard to housing and feeding, and the control generally, and, secondly, because of the inexperience of the coolie in mining. No sooner had the industry fought its way through these difficulties than the Chinese labor question became a political gambling counter, and most unjustly it was decreed that the coolie must be repatriated. Thereupon the old difficulty in regard to native labor was renewed, and the industry suffered a serious misfortune, and incidentally a number of the mines, whose equipment had been increased on the assurance of a full labor supply, found themselves unable to keep their mills adequately supplied with clean milling ore. Wider stoping and the more extended use of machine-drills were adopted to meet the difficulty, with the results already indicated. Unfortunately, the average width of the orebodies of the Main Reef series is low, especially in the higher-grade stopes, and the shattering effect of blasting heavy machine-drilled holes inevitably led to the inclusion of much fine waste-rock that defied the closest sorting operations.

The Interest Charge

From the financial aspect, the increase of milling equipment necessitated the finding of large sums of money and led to watering of capital on a big scale. The money was either obtained by the issue of new shares, or by borrowing at fairly heavy rates of interest. In the former case, the dividends had to be distributed over an increased share capital; in the latter case, profits had to be absorbed over long periods for repayment of the loan. Since the increased profits were not commensurate with the redemption of the increased capital, the shareholder naturally suffered. The issue has been obscured, however, because of the practice of declaring 'working profits' per ton—an arbitrary figure that takes no cognizance of either capital redemption or dividend distribution. A good deal has been written on Rand methods of book-keeping, and it has been shown* that on the monthly profits declared by the various companies approximately only 60 to 80% is actually distributed in dividends. Custom regulates practice in the matters, and once having begun the policy of issuing this form of statement it became almost impossible to alter it. The term 'profit,' however, if it be rightly interpreted, permits of none of these fanciful constructions, and the use of the word on the Rand has, therefore, been incorrect and calculated to mislead. Many mines have been in the habit of declaring 'monthly profits' when the amount of such 'working profit' would not nearly cover a conservative contribution to the interest and redemption fund; in other words, while declaring 'working profits' the company was actually losing money. While there may be, and doubtless is, much to be said from the financial

*In *The Mining Magazine*, for example.

expediency point of view, in favor of running a 'working account' that makes no provision for capital redemption and that permits of independent current capital account, there can be no argument as to what, in the strict business sense, the practice should be. So long, however, as custom permits, there is little probability of a change.

Selective mining, like increased milling capacity is, in principle, easily capable of abuse, although frankly, I am of the opinion that for the Rand a little more of

is found in the deep levels today. In effect, therefore, the average grade of the ore on these levels in comparison with the average grade down to the lowest workable depths would represent a selected product, or, in other words, to reproduce the same average grade of ore from the lower levels, would, under present conditions, require a great deal more selection.

It has been argued, in fact, it is still argued by some, that there is no diminution in the grade of Rand ores as depth is attained, but the argument can hardly be sup-

HEAD-FRAME OF THE CASON MINE, EAST RAND PROPRIETARY, A TYPE OF THE NEWER CONSTRUCTION ON THE RAND.

the former and a lot less of the latter would, all things being considered, have been better. So long as selective mining is followed on the principle which has for its foundation the desire to earn the maximum profit, and into the calculation of which all those essential considerations of capital redemption and working expediency are included, so long and so far will it be profitable. There can be no law laid down for its universal application, because the conditions are never quite the same in any two mines, and each must be figured out on its own merits.

In the earlier history of the Rand, and in the shallower zone, nature had so arranged matters that in most cases selective mining was imperative, that is to say that owing to surface concentration, the proportion of high-grade ore on the upper levels was greater than

ported by a reference to the facts, and indeed it requires only a cursory study of the statistics over the past few years to be satisfied on this point. On several occasions lately I have not hesitated to express my views in this connection in writing, and in 1911 F. H. Hatch, the well known geologist made the following statement:

"I have not been able, with the material at my disposal, to come to any definite conclusion on this point; but I am inclined to the view that a general impoverishment in depth does exist. It would be quite possible, from existing records and assay-plans, to settle this really vital question; but hitherto no figures relating thereto have ever been published by any of the big houses."

It is interesting to note that very recently one of the

largest of the groups† on the Rand included in its technical statements the following:

"There can be no doubt that there is a gradual falling off in the average values over large areas of the ore developed as the deeper sections of the Rand are opened up, and the time will come when the full importance of considering every point which will tend to the lowering of costs for the successful treatment of enormous quantities of low-grade ore, will be realized by the Government and the general public of South Africa at large. This fall in average grade with depth at the individual mines has been shown to be true, not only by the screen samples of the ore milled, and by the re-

tracted from the Chamber of Mines' past records, and dealing with the dividends paid on the capitalization of some of the most successful companies speak for themselves:

| Name of company. | Dividend return on capital. |
|----------------------------|-----------------------------|
| Ferreira | 4415% |
| Crown Reef | 2404% |
| Johannesburg Pioneer | 2107% |
| Wemmer | 1237% |
| Meyer & Charlton | 1105% |
| Durban Roodepoort | 1100% |

As evidence of the magnitude of the operations of some of the companies, the following is interesting:

| Name. | Issued capital. | Tons crushed. | Gross production. | Value per ton. | Dividends distributed. |
|-----------------------------|-----------------|---------------|-------------------|----------------|------------------------|
| Robinson | £2,750,000 | 5,971,075 | £17,378,969 | 58/3 | £9,574,688 |
| Village Main Reef | 472,000 | 5,475,566 | 11,271,376 | 41/2 | 2,911,943 |
| Crown Mines | 940,106 | 15,908,724 | 29,540,128 | 37/2 | 3,807,428 |
| East Rand Proprietary | 2,445,897 | 14,097,016 | 23,157,114 | 32/10 | 3,655,138 |
| Geldenhuis Deep | 585,753 | 10,177,511 | 16,842,039 | 33/1 | 1,969,853 |
| Randfontein Central | 4,193,700 | 10,956,484 | 15,687,985 | 28/8 | 209,685 |
| Simmer & Jack | 3,000,000 | 8,681,486 | 13,122,964 | 30/3 | 4,566,461 |
| Meyer & Charlton | 200,000 | 2,132,701 | 4,026,446 | 37/9 | 1,155,308 |

Note: These are only some of the best; there are many others.

covery value per ton, but by the careful sampling and assaying of level by level in each mine as greater depth was reached, by careful sampling of stopes on each level sending ore to the mill, and by the yearly recast of the ore reserves in each mine."

The mere fact that high-grade ore is still found to occur in the deep levels is of no weight in the argument. The question is one of average width and value per foot of linear development, and the available evidence of a gradually falling grade, so far as my information goes, appears to be overwhelming. But, to my mind, there is nothing extraordinary in this; on the contrary, it is in keeping with all mining history, and is, in the nature of things, to be expected. And surely it is better to have had miles of high-grade ore-shoots of lateral continuity than isolated and narrow vertical shoots descending miles on the dip. The question requires no discussion.

Out of a total production of £347,054,851 from 1887 to 1912, dividends amounting to £88,159,489 have been paid, equivalent to about 25% of the gross production. From 1890 to 1912 the world's production had risen from £24,421,000 to £98,267,000, and of this latter figure the Rand is responsible for roughly 40%. Of the total increase in the year 1912, as compared with the year 1890, therefore, the Rand, single-handed, is responsible for as much as the rest of the world put together—a remarkable record truly, and it is difficult at the moment to see from what source any falling off from the Rand is to be made good, for in the last few years there has been such a dearth of new heavy producers as to make the present outlook rather black.

Some of the individual performances of the Rand mines have been splendid. The following figures, ex-

In a comparison with other goldfields of the world the Rand, considered as a whole, has no parallel, either in the nature of its formation or its magnitude. True, auriferous conglomerate occurs in several other localities in South Africa and also in the United States, but only very limited areas have proved capable of being worked at a profit. The mines of the Rand, with the exception of the main east and west breaks, are divided merely by boundary lines, and the Rand may be looked upon as one immense mine, arranged for division of ownership and convenience of working into a number of small units. At Butte there is something of the sort on a smaller scale in the copper mines; and at Pachuca and other places in Mexico, in silver mines; and at Kalgoorlie in gold mines; but there is nothing really comparable with the Rand. Out of the first 60 gold mines of the world over 30 are on the Rand.

I have been among those who have, in the past, pointed out the advantages of having the mines tied one to the other like a string of beads. The obvious advantages are so obvious that to think anything different at this stage seems rather feeble. But, frankly, I do not feel quite so sure about it, not that I dispute the obvious advantages at all—they are actual without a doubt—but I think that some of the disadvantages that are not so obvious may be just as material or even more so. When two engineers are left to battle by themselves with a given problem, it is possible that they both may arrive at some original solution, but if the two work together on it, the weaker or the less industrious one may be tempted to lean on the other, or, for other reasons, one of them may utterly fail where, if he had been left with the responsibility, he might have accomplished something. A tour of inspection along the mines of the Rand must impress even a casual observer with the fact that there is a faithful reproduction of

†Consolidated Gold Fields report by H. H. Webb of South Africa.

method as between mine and mine. In fact, duplication everywhere is so patent that the observer could not be surprised to learn that the design had emanated from a very few individuals. This in itself might not always be a bad thing, and assuming that the responsible men in charge of the laying out of the development and equipment were invariably right, then there could be no question as to the benefits of the system. But if these men should have been obstinately wedded for sentimental reasons to methods or designs that, from a practical aspect, were opposed to the best knowledge available in other parts of the world, persistence in such an idea might conceivably cause an enormous amount of useless expenditure. Furthermore, the policy of leaving the responsibility of these things in the hands of a few is apt to lead to the stultification of ideas on the part of subordinate engineers.

Engineering Versus Profits

There can be no doubt that a great deal of excellent work has been achieved on the Rand from the engineering standpoint, but it cannot be denied that the expenditure on capital account has in many cases grown out of all proportion to the real requirements, and to some extent the proximity of the mines to each other is responsible for them. While the metallurgists of the Rand have been spending millions in covering large areas with heavy, expensive, and cumbersome percolation cyanide-plants, and decantation slime-plants, other countries have been able successfully to evolve, under much more trying conditions, and often with meagre financial resources, new systems of treatment on more complicated ores even with great profit. The Rand, since the introduction of the cyanide process in the early days, has done practically nothing to add to the glory of engineering achievements. It has rather followed a policy of sticking to the one old principle and developing the details of that principle to the last limit. In my opinion, and I share this with a great many other engineers, the Rand might have saved itself a large amount of capital outlay if it had adopted immediately after the war, for the treatment of its unusually simple clean ores what has been accepted all the world over in the last ten years, namely, the one-product one-treatment method. The real truth of this matter is obscured by the fact that metallurgical working costs do not on the Rand take into account the amortization of capital expenditure, and, therefore, no matter how absurdly high that expenditure may have been, the real meaning of it has not been realized. It would be safe, however, to say that there are instances on the Rand in which, if this principle be applied, the redemption figure per ton treated would amount to almost as much as the stated figure of 'working cost,' and it is just as real a figure, although not shown, as the other one. If the mines of the Rand had been more isolated, individual effort would have been greater, competition keener, methods more original, expense much less, and profit correspondingly much greater. I am making no personal attack in these remarks, being

in many respects perhaps as responsible, and therefore as blameworthy as many others, but I put it down to a system that could only have arisen out of the proximity of the mines.

In heading these notes 'The Decline of the Rand,' it must not be inferred that I am pointing to any precipitous ending of the industry; I believe firmly, as before stated, that the Rand will die very hard, and, for many many years to come, it will hold the place of pride in the world's gold production. It is not possible, of course, to foresee what new methods may arise in the treatment of ores to lower the cost of production, but it may be taken for certain that as the margin between expenditure and revenue becomes narrower, so will the effort to keep them apart increase, and ways and means that are not known today will be born of necessity to keep the industry still alive. It is fashionable to talk about the possibility of treating the untold millions of tons of ore lying in the Kimberley Reef series, and it is a fact that even up to now this series has been able to produce quite an appreciable tonnage of pay-ore. There is always, however, a limit to what is feasible under given conditions, and the one great limiting factor of the Rand is the comparatively narrow average stopable width. To get tonnage on narrow orebodies means extensive development, and costly mining, and even with heavy reductions in the cost of materials such as explosives and so forth, one cannot at present see that it can ever amount to enough to make 2 or 3 dwt. ore cover all expenditure, and return a reasonable interest on the money invested. Failing the discovery of new deposits therefore, the end, though not in sight, is within the limits of approximate calculation even after liberally discounting for new unforeseen favorable conditions.

Decline in Speculation

Probably the worst feature of the decline is that speculative interest gradually dies out, and it is difficult to interest the public sufficiently to get their purse-strings loosened for new capital requirements.

With the channels of fresh capital dry, the encouragement to lay out money on attempting new expedients for the reduction of working costs is little, and those now in financial control will probably be inclined rather to keep down all new capital expenditure to the narrowest limits, leaving the bulk of the present producing mines to end their lives with the barest maintenance of their existing equipment. This, of course, is always assuming, as before stated, that there is no new and startling discovery of some unforeseen nature, favorably affecting the question of working cost, because, after all, that is the crux of the whole of the problem now facing the Rand. My summarized reading of the indications is that the gross output, like the dividends, will soon begin to decrease, and the drop will be steady, though sure.

Finally, the Rand industry is like a great man who even in his declining years has still stood head and shoulders above everybody.

Hydro and Pyro-Metallurgy of Copper in 1913

By THOMAS T. READ

I. Hydro-metallurgy

It is somewhat illogical to place the discussion of the hydro-metallurgy of copper before that of ordinary smelting methods. But this reversal is perhaps justified by the present keen interest in wet methods for the extraction of copper from its ores, arising from the necessity for devising some means to recover the copper present in the form of oxidized minerals in the enormous tonnages of low-grade ores now being mined and milled in many different places. The oxides, carbonates, and silicate of copper are all rebellious both to ordinary wet concentration and to flotation, and the use of hydro-metallurgical processes seems the only possible means of effecting the recovery of their copper content. The general criteria of the hydro-metallurgy of copper has been discussed at some length in these columns on several occasions,¹ and needs no further references. All the most promising

of recent work has centred around leaching in sulphuric acid solution. The simplest method, to be applied on the largest scale, is that proposed for the brochantite ore of the Chile Copper Co. at Chuquicamata. This has already been described at some length,² but may be summarized by saying that careful large-scale experimental work done by E. A. C. Smith has demonstrated that the copper content of this hydrous sulphate of copper can be extracted by leaching the ore, after crushing to 3-mesh, with 8 or 9% sulphuric acid solution. This is to be done in concrete vats holding 9000 tons each, and it is estimated that one day will suffice for filling, two or three days for leaching and washing, and one day for discharging, which is to be done with clam-shell buckets. The copper in the pregnant solution will be precipitated electrolytically, a 40,000-kw. generating station on the seacoast and a 100-mile transmission line being already under construction. This ore contains no gold, silver, bis-

BRADEN MINE, MILLS, AND SMELTER, RANCAGUA, CHILE.

muth, arsenic, or antimony and, being a sulphate, the solution builds up in sulphuric acid, so that acid consumption is *nil*. Small amounts of chlorides and nitrates are present and cause difficulties which have been successfully overcome, but the means by which this is done have not yet been disclosed.

Leaching work at the Braden has been delayed by more urgent problems, and the necessity of using the available electric energy for other purposes. E. A. Cappelen Smith has recently described the proposed process as follows: "The process decided on was roasting of the concentrate in a Wedge furnace in such a manner as to eliminate practically all of the sulphur and at the same time oxidize all the iron to the ferric state. The concentrate, after roasting, contained 2 to 3% sulphur, practically all in the form of sulphate, 15 to 18% copper, and about the same amount of iron, of which only a very small amount was present in the ferrous state. The roasted concentrate was leached with dilute sulphuric acid, the leaching operation being divided into two stages: first, neutralizing leaching; second, acid leaching. The solution from the neutralizing leaching was electrolyzed direct, whereas the solution from the acid leaching was neutralized by the following batch of calcines. Several leachings made in the plant indicate an extraction of between 90 and 95% of the copper present in the concentrate."

Leaching at Butte

The most interesting announcement of the year³ was that roasting and leaching with sulphuric acid, following a method devised by Frederick Laist, was to be tested on a large scale for treating the tailing from wet-concentration processes at Anaconda. An 80-ton experimental plant was constructed, and the results of the first work were published⁴ during the summer. As this paper is readily accessible and contains many important details, it should be read by all. Briefly, the process consists in drying the tailing from wet concentration on the upper hearths of a McDougall roaster, adding salt, and roasting at a low temperature to keep down the volatilization of copper chloride and the production of ferrites. The calcine is then leached with sulphuric acid solution. Experimental work later in the year has been highly successful. It was at first proposed to precipitate the copper from this solution by H_2S , thus regenerating H_2SO_4 , but more recent work indicates the desirability of using an iron sponge produced by reducing 20-mesh calcine with coal dust in a McDougall furnace. The sulphuric acid required for leaching is to be made in lead chambers, from the SO_2 gas obtained in roasting rich coarse concentrate, at an estimated cost of \$4 per ton. Tentative plans for a 2000-ton plant are well advanced. As a result of the success of this work experiments along similar lines are being made at several places.

In preceding years I have usually closed the dis-

DAM AND INTAKE HOUSING, CACHAPOAL RIVER; BRADEN POWER PLANT.

cussion of this topic with an expression of hope that by the following year details of the practical operation of leaching plants would be available. That hope has at last been rewarded, P. E. Peterson⁵ having published descriptions of the Butte-Duluth and Bullwhacker plants, which were erected at Butte last year. It is to be deplored that these descriptions do not include any account of the numerous difficulties encountered in the early operation of these plants, as being more helpful to operators elsewhere than the methods found successful. These plants operate under special conditions, in that they treat silicious ore comparatively free from the iron oxides present in ordinary oxidized ores. The Butte-Duluth plant is 100-ton and

where it is heated to 60°C., and thence to the electrolytic cells. Each of these is 30 by 39 in. and 8 ft. long, lined with hard lead, and provided with 20 anodes of hard lead, weighing 20 lb. per square foot. The cathodes are ordinary starting sheets of copper. The current density used is 12 to 13 amperes per square foot, and the cathodes assay 99.96% copper, according to Mr. Peterson. The present cost is estimated by him as 14c. per pound of copper, but he thinks this can be considerably reduced, as the sulphuric acid required now costs \$27 per ton or 43¼c. per pound of copper produced. If locally manufactured on a large scale, the sulphuric acid should not cost over 1½c. per pound of copper. The percentage of extraction on the ½-in. ore was so low that it was necessary to abandon that method and for a little over two months now the following process is being successfully carried on.

The Company is building at the present time a 1000-ton dry-crushing plant to reduce the ore to 10 mesh. This consists of swing-jaw crusher, intermediate gyratory crusher, Symons disc crusher, rolls, and impact screens. The dry ore is fed to a mixer with

ORIGINAL FLOW-SHEET, BUTTE-DULUTH PLANT.

the Bullwhacker 125-ton. In the former the ore is crushed, by gyratory and Symonds disc crushers, only through a ½-in. screen; in the latter it is reduced by rolls until it passes 16 mesh. The ½-in. ore is dumped into V-shaped leaching vats, provided with a filter bottom of boards bored with 5/8-in. holes. After leaching with acid, the vats are discharged through doors in the bottom. The solution is drawn from the vats, allowed to settle, elevated to lead-lined tanks,

CENTRAL MONTANA.

⁵Min. Eng. World, Sept. 6 (p. 423) and Oct. 4 (p. 585), 1913.

approximately four times its weight of 8 to 10% sulphuric acid which discharges to a Dorr classifier, which is the first of a series of 6 arranged in such a manner that the sand will discharge from one into the next. Various times of contact with the acid in the first four Dorr classifiers were tried out and it was found that approximately 40 minutes gave an extraction between 85 and 90%. The last two classifiers, No. 5 and 6, in the series, are used for washing. The overflow from No. 5 is used to make up for the loss of acid in the strong acid solution.

The overflow from No. 1 classifier carries off approximately about 13% of the total weight of ore as slime. This, as well as the overflows from classifiers 2, 3, and 4 are run to the acid leaching-tanks in the bottom of which is a layer of crushed ore to act as a filter. The underflow from these filters passes to the electrolytic cells and on to the strong acid storage-tanks where the solution is brought up. This method of running the slime to the acid leaching-tanks is only temporary as later on it is intended to recover the dissolved copper content by passing this pulp through a series of Dorr continuous thickeners operated so as to give counter-current washing.

Handling Acid Solutions

The second water wash, which is applied to the last classifier, goes to scrap iron precipitation. The sand discharged from the classifiers approximates 18 to 20% moisture. No. 1 classifier in the series is a machine 30 ft. long by 4 ft. 6 in. wide. The rest of the classifiers are of standard duplex size, 15 ft. long by 4 ft. 6 in. wide. These machines are built with wooden boxes and all moving parts that come in contact with the acid, also built of wood (hard maple). The wear of the wooden teeth is surprisingly small, but experimentation has shown that plate glass teeth are the proper thing to use here, and will be installed in any future classifiers built for this purpose. This series of 6 classifiers is operating at the present time and has a capacity of approximately 200 to 220 tons per 24 hours.

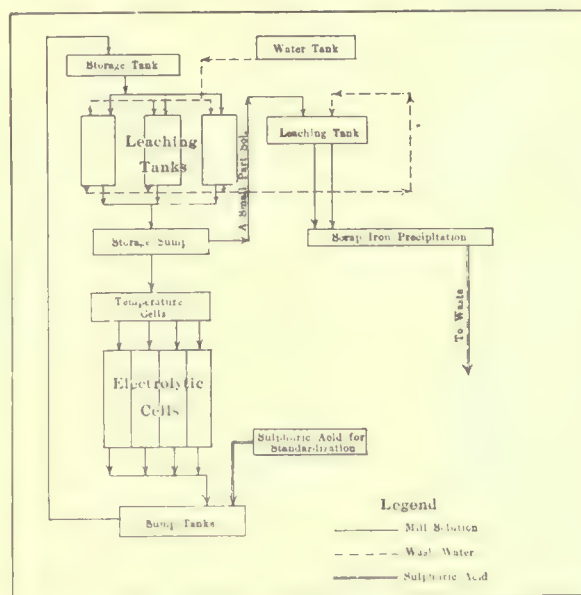

The Dorr Cyanide Machinery Co. is building another series of 5 machines each 30 ft. long by 8 ft. wide, which should have a capacity of 400 to 500 tons of ore per day. At the present time strong acid solution is being added with the ore to No. 1 classifier, but later on this practice will be altered and the overflow from No. 5 Dorr classifier will be mixed with the dry ore; the advantage of this being that the strong solutions can be kept from coming in contact with the slime, the weak acid solution not taking iron and aluminum into solution so readily as the strong. All solutions in the plant are kept at approximately 55° C. The cost of this in the northern winter climate is likely to form a considerable item of the total working cost.

At the Bullwhacker plant, which is near by, the ore, crushed to 16 mesh, is agitated with 10% H_2SO_4 solution, 2 tons of solution to 1 of ore, in a Hendryx agitator. This agitator is to be replaced by Dorr classifiers when the plant is enlarged. The effluent solu-

tion, containing as much as 4 to 5% copper, is decanted from settling tanks, and sent to electrolytic cells which differ from those previously described in being circular, 9 ft. in diameter and 5 ft. deep, holding 24 cathodes. About half of the copper content of the solution is deposited electrolytically, and it then goes back to be used for further leaching. The cost of production of copper is here also about 14c. per pound.

Difficulties in Leaching

The difficulties of the method employed in these two mills are, perhaps, not unnaturally, not discussed at length. They may be summarized as follows: fine crushing is necessary in order that the copper minerals shall be completely soluble, but leads to the production of colloids ('slime') which make the solution cloudy and difficult to settle. It is, of course, impossible to deposit a pure cathode from a solution containing impurities. The leached ore is difficult to wash for the same reason, and also because the use of wash-water involves the discharge of solution, which car-

FLOW-SHEET, BULLWHACKER PLANT.

ries away with it not only the expensive sulphuric acid but copper as well. This copper can be precipitated on iron, but the consumption of iron by the acid cuts down the net return. The difficulties and excessive consumption of energy in precipitating copper electrolytically when using an insoluble anode are too well known to need repetition. Here the resistance of the solution has been decreased by preheating it, and its conductivity is kept as high as possible by only precipitating half of the copper present. At several other mines, notably the Nevada-Douglas, preparations are being made for the construction of similar plants, but it is not to be expected that these can be put into operation without first solving local problems.

At nearly every important copper mine in the West some member of the chemical or metallurgical staff is

studying hydro-metallurgical problems in the light of local conditions. The work at the Shannon, Calumet & Arizona (Ajo), Arizona Copper, and Braden mines was described in my review for last year, and no reports of progress have since been given out. At the Keystone and Inspiration, both a Miami, interesting work is being done. J. Parke Channing has described this work in the *Bulletin* of the Mining and Metallurgical Society of America. R. C. Canby, at the Keystone, suggests the possibility of using cast-iron hearths as at the Steptoe Valley smelting plant, later mentioned, in the McDougall roasting furnaces, so that the fuel used on one hearth would better heat those above. He proposes to use a special design of burner which will permit the use of oil as a fuel along with the maintaining of a low temperature on the hearth. At the Copper Queen the leaching of low-grade ores is also being studied.

Leaching at Ray

W. Y. Westervelt describes in some detail, in the November *Bulletin* of the Mining and Metallurgical Society, the following record of a 33-day test on the average ore at the Ray mine in Arizona.

"The ore in the vats at the beginning of the tests was carefully sampled and assayed by the vat. That added during the test was weighed, sampled, and assayed by the vat charges of 200 lb. each. Tailing rejected during the test was sampled, and assayed by the vat discharged. The ore remaining in the vats at the end of the test was sampled and assayed by the vat.

"At the beginning of the tests the solutions in the vats were carefully drawn off, measured, and sampled. The same was done independently with that in the electrolytic tank, and again independently with that in the storage tanks. All acid added (commercial 66° B. sulphuric acid) was carefully weighed as added. Additions of water were measured, the condition of the solution was daily determined by assay, and on completion of the test, complete measurement and assay was again resorted to.

"The electrolytic copper was deposited on copper cathodes previously made from the Ray ore by stripping the deposition on rolled copper sheets. These cathodes were removed and weighed daily. The voltage maintained at the tank was determined hourly by a Weston voltmeter capable of being read to 0.01 volt. The amperes were determined both by hourly readings of a Weston ammeter and by checking against the daily weighings of a standard copper voltmeter.

"The heating was done solely in the leaching vats by means of closed lead-pipe coils placed in the bottoms. Steam was supplied to these coils from a main line running over the five vats and the condensed water was all secured by connecting the ends of the coils with the main drain pipe, the latter itself discharging into a measuring can. The steam supply was regulated by a valve to each coil, as was also the discharge into the drain pipe, by another valve. The drain pipe itself, in which the condensed water accumulated, was kept

closed by a valve so that no uncondensed steam could escape.

"The ratio of volume to surface of the vats employed was 3.03, while that of 26-ft., 100-ton vats is 0.487, or less than 1/6. In other words, the heat radiating and conveying surface of the experimental plant was over six times as great proportionately as would be that of a 100-ton vat plant. Again, the evaporative surface of an operating plant would not be 1/4 as great proportionately as that of the experimental plant, while a considerable part of the steam condensing surface in the experimental plant was outside the vats, thus doing no

MAP OF ARIZONA.

work, while registering as condensed steam. Due allowance was accordingly made for these which may be summarized as below:

| | | |
|--|----------|------|
| Copper deposited, total run | 40.28 | lb. |
| Copper deposited, per diem | 1.22 | " |
| Amount ore in vats | 1000.00 | " |
| Copper deposited per diem, per ton in vats (0.122%) | 2.44 | " |
| Days required to extract 40 lb. per ton | 16.4 | days |
| Acid consumed | 91.4 | lb. |
| Acid consumed per pound copper deposited.. | 2.27 | " |
| Ampere-hours consumed | 22,382 | |
| Ampere-voltage | 1.7 | |
| Kilowatt-hours | 38,049.4 | |
| Kilowatt-hour per pound copper | 0.945 | |
| Ampere-hours consumed per pound copper.... | 556.0 | |
| Steam condensed per pound copper deposited. | 33.0 | lb. |
| Extraction | 80% | |
| Average temperature of vats | 72°C. | |
| Assay of tailing | 0.3% | |

The Bradley leaching plant at Anaconda has

closed down, having proved a failure. The various other patented processes seem not to have made much headway during the year. The McKay process, which is now being developed by Archibald Carmichael, was under investigation by important interests, but it is reported that negotiations have been dropped. The owners of the Alexander process are carrying on experiments, but have made no report of progress. The same may be said of the Robertson process. The Irving process is elsewhere described by L. S. Austin. The leaching of the copper contained in the burned cinder from sulphuric acid making is being done in a number of places, but is quite a different operation from the leaching of raw or roasted ore. In the precipitation of copper from mine-water, J. W. Richards has suggested that if the scrap iron used for this purpose were laid upon sheets of copper, a galvanic couple would be established and the surface of the iron kept cleaner and consequently more efficient. It is proposed to use sponge iron for this purpose in place of the usual scrap iron, but the experiment has not yet been made. In conclusion, it may be said that the experimental work at Anaconda has demonstrated the possibility of roasting sulphide tailing at a low cost, and the leaching plants at the Bullwhacker and Butte-Duluth have demonstrated the practicability of sulphuric acid leaching and electrolytic precipitation for oxidized silicious ores, with prospects of attaining a low cost. It must not be forgotten, however, that local conditions create fresh problems at each mine.

II. Pyro-Metallurgy

The year 1913 has been made notable in copper metallurgy by the great number of important papers on that subject which were called out, largely through the efforts of B. B. Thayer and C. W. Goodale, in connection with the meeting of the American Institute of Mining Engineers. These papers contain so much of interest that it is impossible in the space available to discuss them in any detail. In blast-furnace smelting, J. A. Church, Jr.,⁶ has described the development of the blast-furnace at Great Falls, Montana, to a width of 7 ft. R. P. Roberts⁷ has discussed the thermal effect of blast-furnace jackets. The problems of blast-furnace smelting at high altitudes has been discussed by Vincente Pazos y Sacio,⁸ who points out how the decrease in pressure due to altitude decreases the temperature of combustion within the furnace so that "oxidizing smelting in Peru today is nothing but pot-roasting carried to fusion at the expense of fuel." He suggests the use of back pressure on the blast-furnace, hot blast, and the reducing to a minimum of radiation and conduction losses. Herbert Lang has discussed⁹ the possibility of the use of crude oil in blast-furnace smelting, but no new experimental data have been made public during the year. The use of electric

furnaces in the smelting of copper ores is being exhaustively studied by the United States Bureau of Mines, and D. A. Lyon and R. M. Keeney, who are in charge of this investigation, presented a preliminary paper¹⁰ at the Montana meeting of the Institute, and a general discussion of much interest before the Denver meeting of the Electrochemical Society.¹¹ I have already discussed¹² this at some length. The metallurgical profession is greatly indebted to the Bureau of Mines for undertaking the study of so timely a topic upon a scale which would not be practicable in connection with ordinary metallurgical operations

Roasting

Two important papers on roasting have appeared during the year. S. S. Sorensen has described¹³ the roasting practice at the Steptoe Valley plant, where, in order to economize on the heat balance when roasting concentrate low in sulphur, air cooling was substituted for water by boring holes in the rabble arms and blowing air through them, at 2½-in. pressure, by the aid of a fan. Oil-firing was substituted for coal, and the lowest hearth was made of cast iron. As a result of these improvements the tonnage roasted was raised from 50 per day to over 100. These are 18-ft. McDougall furnaces. F. R. Corwin and S. S. Rogers have described¹⁴ the carefully conducted experiments by which the tonnage of the 16-ft. Evans-Klepetko furnaces at the Great Falls smelter was increased from 45 to over 100 per day, the limit being apparently the mechanical strength of the apparatus. This paper is full of valuable experimental data and should be consulted by everyone interested. I can only mention a few interesting points. The tests were first directed to merely increasing the tonnage roasted per furnace day, and it was found that this could be doubled by supplying sufficient oxygen, regulating the heat so the furnace would not get too hot, and by regulating the drop-hole area so as to avoid too great concentration of heat and too high a velocity of the gases through the drop-holes, which leads to the building up of heavy crusts on the roof of the hearths. The maximum proportion of screened raw ore to concentrate was then studied. By the use of compressed air, blown in through small pipes placed beneath the roof of the fourth and fifth hearths, and about 6% of slack coal mixed with the ore in the feed hoppers, raw ore containing 17½% sulphur could be roasted without the addition of any high-sulphur concentrate. The next investigation was directed at decreasing the amount of flue-dust made in roasting, with the result that by properly proportioning the drop-holes and by using 'spark-

catchers' to prevent incrustations on the hearth roofs, the amount of flue-dust made was reduced from 18% to about 10% of the weight of the charge. Finally, reinforced concrete was substituted for brick in the hearth construction, with the result that repairs were greatly decreased, and incrustations were more easily removed.

In the field of reverberatory smelting, the most important paper of the year is that of S. S. Sorensen,¹⁵ who has given the result of a 3-months' comparative test of Sterling and Babcock & Wilcox boilers for the recovery of the waste heat of the gases in reverberatory smelting. This test showed that although the Sterling boiler is much more easily cleaned, the Babcock & Wilcox gives nearly 20% greater efficiency as a result of better arrangement of the tubes. I have already reviewed¹⁶ reverberatory smelting practice in the southwestern United States and will not again refer to it here. (Since this was written the reverberatory furnaces at the Calumet & Arizona and Arizona Copper smelters have been blown in, but none of the results attained have as yet been made public.) The substitution of coal-fired for gas-fired reverberatories at the Great Falls smelter is in progress, but none of the furnaces have yet been blown in. Presumably some interesting new data on reverberatory smelting will be available next year. As usual, L. D. Ricketts has given interesting data in his annual report of the operations of the Cananea Consolidated Copper Co. During 1912 the smelter handled 653,595 tons of new copper-bearing material at a cost of \$2.48 per ton. The reverberatory furnace handled 145,970 tons (62,147 tons flue-dust, 52,541 calcine, and 31,282 tons Miami concentrate) at a net smelting cost of \$1.66 per ton. The average charge per furnace day was 223 tons. These furnaces are 19 by 100 feet.

Sintering

In regard to the handling of fine ore, there is a tendency toward the increased use of Dwight & Lloyd sintering machines, good results in handling the sulphide in this way having been attained at the plants of the Tennessee Copper Co., which is using three machines, the Cerro de Pasco, which has six, and the Tacoma and Trail smelters, which have two each. The Mond Nickel Co. has recently started a single machine on its fine ore. The use of these machines to sinter flue-dust was discussed in my review of the subject for last year. R. L. Lloyd has published¹⁷ an interesting discussion of the criteria of sintering at high altitudes, and brings out the interesting fact that at 14,000 ft. elevation ore carrying as high as 25% sulphur can be sintered without the generation of excessive heat. It is also interesting to notice that at the new Arizona Copper plant two mixing cones¹⁸ will be used to mix fine silicious

material with converter slag before sending them both to the reverberatory furnaces. In this way the excess iron in the converter slag is to be made to serve as a flux for the excess silica of the fine. Converter slag continues to be a bugbear and nearly everybody pours it back into the reverberatory furnace or through the blast-furnace settler so that it will not hurt the professional pride of the technical staff, as it would do if allowed to run directly to waste. Where converter slag can be chilled and added to the blast-furnaces it doubtless serves as a flux, but, except for keeping the charge easily fusible, its rehandling offers little.

Converting

Converter practice has changed little during the year, except that at the plants where converters of the Great Falls type have recently been constructed the workmen and technical staff have learned by experience the details of their control. The Pierce-Smith converter has apparently regained some of the regard which it seemed about to lose last year, and in several plants very good results have been attained by its use. Converter practice at Great Falls has been described by A. E. Wheeler and M. W. Krejci.¹⁹ This should be read by every copper metallurgist. In the following discussion a number of other important points were brought out by other metallurgists. E. P. Mathewson²⁰ described the development of the basic-lined converter and Ralph Baggaley²¹ controverts his statements. It seems but just to believe that Mr. Baggaley should have the credit for first successfully maintaining a basic lining and supplying the necessary silica by the addition of ore, but his work was so mingled with financial disaster and the use of impractical forms of equipment that there will always exist a difference of opinion as to whether he made a success or a failure. None of those who developed the basic-lined converter perceived, until after success had been attained, that the essential feature is to use a large enough mass of matte so that its temperature can be maintained and controlled. In an interesting review of the development of converter practice,²² Herbert Haas has pointed out that Paul David deserves equal credit with Pierre Manhés for the first successful work in producing copper from matte in a converter, and draws attention to the fact, too often overlooked, that Hollway, in his classic experiments, was not attempting to make copper from matte, but to smelt sulphide ores without the use of fuel. Hollway should therefore be regarded as the pioneer in pyrite smelting, rather than in converter practice.

Smelting Mixed Sulphides

The treatment of complex mixtures of copper and zinc sulphides has been described at some length²³ by

¹⁵*Mining and Scientific Press*, Oct. 11, 1913; see comment by Hervey Gulich, *Mining and Scientific Press*, Nov. 23.

S. E. Bretherton, who proposes to use, at Ingot, Shasta county, California, the Schnabel process of extracting zinc as oxide from the roasted ore by the use of ammonia and carbonic acid, smelting the leached ore in a reverberatory furnace. H. O. Hofman has pointed out²⁴ that this process was tried at Lautenthal, in the Harz mountains, and at Hoboken-les-Anvers, with the result that it was found impossible to compete with retort distillation. W. McA. Johnson has announced the successful conclusion of a large amount of experimental work which he has done at Hartford, Connecticut, in developing a continuous zinc furnace in which the zinc is distilled off, while the copper or lead present is drawn off as matte or bullion. It is expected that one of these will be put in operation in California during the coming season, and the comparative results of the two methods will be watched with the keenest interest.

Smelter Fume

The event of the year in advancing toward the solution of the smelter fume problem was the announcement²⁵ that the Hall process for the roasting of sulphides without the production of SO_2 was to be tried at the smelter of the First National Copper Co., Shasta county, California. This process consists in so controlling the temperature and admission of oxygen and steam into a roasting furnace of the McDougall type that the metals are oxidized while the sulphur is not, but distilled off and caught as flowers of sulphur. The early experiments were handicapped by troubles with the gas-producers used for making gas from crude oil, but these have been overcome and the outlook for eventual success seems bright. J. Nelson Nevius has published²⁶ a thoughtful study of the conditions in Shasta county, California, made for the Los Angeles Chamber of Mines and Oil. Edgar M. Dunn has described²⁷ the methods for the determination of the gases and dust in smelter flues in an important paper. James Elton²⁸ described the methods of the recovery of As_2O_3 from flue-dust practised at Anaconda, and C. W. Goodale and J. H. Klepinger have published²⁹ a detailed description of the Great Falls flue system and chimney, which is full of interesting details. The metallography of refined copper has been discussed by E. S. Bardwell.³⁰ The electrolytic refining of copper is mentioned elsewhere in this issue.

Actual progress, it is but fair to say, in the metallurgy of copper has probably not been much more rapid this year than in preceding ones, but the year has been made a red-letter one by the generous way in which metallurgists have contributed from their experience to advance the general good.

Electrometallurgy in 1913

By G. A. ROUSH

The advances in the various lines of electrometallurgy are so numerous, so diverse, and so widely scattered in the literature, that in the preparation of a review of this kind, all one can hope to do is to select some of the more striking discoveries in the more important fields to serve as illustrations of the general trend of the industry. What the breadth of these advances has amounted to, as measured from time to time, can probably be fully appreciated only when one considers the enormous development of electrometallurgy as it stands today, and measures up against it the comparatively short span of years through which this development has extended. By thus setting up the milestones, as it were, one secures a better idea of the general perspective into which this brief sketch of recent progress must fit.

Copper

So far as the current literature shows, there are no copper ores being treated at the present time in the electric furnace in this country. Trial smeltings of copper in a 1000-hp. furnace with an estimated production of 2000 tons per year have been reported from the Ilen Smelting Works at Trondhjem, Norway, but no detailed data concerning these experiments have been found.

An article in *Elec. Rev. West. Elec.*¹ describes electric copper smelting tried at Globe, Arizona. Test runs showed an extraction of 98% of the copper content of the ores. The furnace was of the vertical-shaft resistance type, 6 ft. in height, and lined with magnesia bricks. The opening of the furnace was 22 in. diameter at the top and 20 in. at the bottom, with a 5-in. Acheson graphite electrode swung at the top and a stationary electrode fixed at the bottom. Heating was started by an arc, and continued as resistance heating as soon as the charge was sufficiently melted. The power required was 3500 kw-h. per ton of charge.

Stephan² gives an account of experiments on the reduction of copper and nickel in furnaces similar to the Girod steel furnace. It was attempted to reduce a copper oxide ore high in silica and carrying some iron and cobalt, using solid carbon as a reducing agent, and limestone as a flux. A continuous run of several days resulted in a power consumption of 1000 to 1200 kw-h. per ton of ore. This figure is high on account of the high temperature required to keep the very viscous slag fused. With a more easily fluxed ore, the power consumption was as low as 500 kw-h. Charcoal, coke, and anthracite, to the extent of 25% of the copper in the charge, were all used successfully as reducing agent. The pig copper produced carried

¹Volume 63, page 636.

²*Metall. u. Erz.* Vol. 10, pp. 11-17, 84-86; *Met. Chem. Eng.* Vol. 11, pp. 22-23.

65 to 95% Cu, 1 to 21% Fe, and 1 to 11% CO, depending on the temperature conditions in the furnace. The lower the temperature, the smaller was the amount of impurities reduced, but the larger the loss in unreduced copper.

Lyon and Keeney³ report a series of experiments on the smelting of copper in the electric furnace. Experiments on sulphide ores, where the smelting consists simply in melting down the ore, volatilizing out sulphur, and separating the slag and matte, indicated that in a furnace of commercial size the power consumption would be about 480 kw-h. per ton of ore for a low-grade ore producing a matte carrying 1.22% Cu. There was some loss of silver by volatilization, but very little gold or copper. The authors conclude that the smelting can be done as efficiently in the electric furnace as in the reverberatory or blast-furnace, and the desired reactions can be carried out as satisfactorily.

This does not include patents granted on a number of different forms of electric furnace, and various electrometallurgical processes, concerning which nothing is known outside of the patent claims.

On the whole, the problem of the electric furnace reduction of copper seems now to be on about the same ground as the electric furnace reduction of iron was a few years ago. It is largely a question of the substitution of electric heating for carbon heating, which means that it is largely a question of the comparative cost, at a given locality, of electricity and coal or coke, and the relative efficiency with which they can be utilized. The electric furnace under these conditions is not the competitor of the combustion furnace, but a substitute for the combustion furnace under certain conditions.

Electrolytic Refining

Burns⁴ describes experiments on the electrolytic refining of copper precipitate anodes. About 1400 tons of copper precipitate was melted down in the reverberatory furnace, about 25% of the charge being anode scrap, etc. The results showed that wire bar copper could be produced from these anodes at a current density of 17 to 18 amperes per square foot, while ingot grade copper is produced at a current density of 33 to 35 amperes per square foot.

Peterson⁵ describes the leaching process of the Butte & Duluth Mining Co., Butte, Montana. These ores are oxidized varieties, carrying about 2% Cu, readily soluble in dilute sulphuric acid. Leaching with 10% acid for 24 hours dissolves the copper from the ore, and the acid solution is then electrolyzed, recovering the copper and regenerating the acid, which can then be used for further leaching, after the addition of sufficient acid to restore the original concentration, and make up for losses throughout the process. This

amounts to about 3½ lb. of acid per pound of copper recovered. The power used is about 1 kw-h. per pound of copper. The copper produced analyzes about 99.96% pure.

Then there is the sulphatizing roasting of copper ores, followed by leaching and electro-deposition. Sulphide copper ores are roasted under conditions giving a maximum formation of sulphate. In this way 93 to 95% of the copper content of the ore can be made soluble in dilute sulphuric acid. The acid leach solution is then electrolyzed for the recovery of the copper and the regeneration of the acid, which can then be used for further leaching.

Zinc

Of all the different metals that are being treated by electro-metallurgical processes, probably none has been the subject of more discussion than zinc. Iron and steel take precedence over zinc only in the importance of the greater tonnage involved. Zinc secures this attention because of the proportionately small amount of progress that has been made in recent years along the lines of the present standard methods of treating zinc ores, and the possibility, not only of developing a process that can be run at a better efficiency than the present pyro-metallurgical methods, but also the possibility of securing a method of treating ores that cannot be treated at all by the present methods. And it is in this latter field that the electro-metallurgy of zinc promises the most satisfactory returns, at least for the immediate future. Numerous patents on furnaces and processes have been granted during the past year, but as little is known concerning most of these, beyond the claims stated in the patent, I will confine myself to the various publications of the past year giving the results of experimental work and information in regard to the general condition of the electro-metallurgical side of the zinc industry.

Uebbing⁶ describes two methods of working a zinc-bearing burned pyrite. The first method was by a reducing smelting in an electric furnace, using CaO to assist in slagging the sulphur. Most of the zinc was volatilized from the charge, and the iron was obtained as pig iron. In order not to have too much sulphur in the pig iron, it would be necessary to reduce the sulphur in the raw material to less than one per cent. The second method consisted in reducing the sulphur by further roasting, briquetting the pulverized material with tar or pitch, and heating. A preliminary baking produced a part reduction, and subsequent heating in a vacuum furnace at 1000 to 1100° reduced all the iron and distilled out the zinc.

On account of the low cost of power, the Scandinavian countries have progressed further in the commercial application of electric zinc-smelting than have any of the other countries. There is one plant in Sweden, one in Norway, and it has been recently reported that a plant has been started in Finland, using 2500 hp.,

³Bull. No. 80, Amer. Inst. Min. Eng., pp. 2117-2149.

⁴Bull. No. 79, Amer. Inst. Min. Eng., pp. 1163-7; *Min. Eng. World*, Vol. 39, pp. 469-70.

⁵*Min. Eng. World*, Vol. 39, pp. 423-5.

⁶*Metall u. Erz*, Vol. 10, pp. 1 and 607-611.

which is to be later increased to 6000 hp. In the *Australian Mining Standard*⁷ it is stated that the Sulphide Corporation has constructed at Cockle Creek, New South Wales, a 500-hp. electric furnace for the electric smelting of zinc, combined with the manufacture of sulphuric acid and superphosphate.

A recent report of the directors of the Hydraulic Power & Smelting Co., Ltd., gives the following information in regard to Scandinavian zinc smelting. The capacity of the works at Sundlokken (Sharpsborg), Norway, has been increased from 8000 to 10,000 tons per year, and contracts for the sale of the entire coming year's production have been made under terms giving a satisfactory profit. The erection and equipment of a new plant at Trollhättan, Sweden, is being pushed as rapidly as possible, and 13 furnaces of 1000 hp. and 8 of 500 hp. have been installed. Five more 1000-hp. furnaces will be built.

The problem of electric zinc-smelting is being studied in Canada under the direction of Stansfield and Ingalls, under a grant from the Canadian Government, but no recent publications have been made by them. The leading investigators in this country are Johnson and Peterson, both of whose processes are described in considerable detail in papers presented at the Denver meeting of the American Electrochemical Society, September 1913.⁸

Zinc Smelting Near

While there have been no radical improvements in the various processes for the electric smelting of zinc during the past year, the gradual advance of the experimental and semi-commercial processes that are being tried out seems to lead to the conclusion that for complex ores, where the recovery of the zinc must be accompanied by the simultaneous recovery of copper, lead, silver, and gold, electric smelting processes show decided possibilities. After considering the various sides of the question, Ingalls comes to the conclusion that if the zinc can be smelted with an expenditure of not more than 1200 kw-h. per ton of ore, the electric smelting processes will become a possibility worth considering. Johnson, in the article cited above, publishes values of kilowatt-hours per ton ranging from 1100 to 1700, and expects to secure still better results with further development of his process, and, with larger size furnaces, Peterson figures on a basis of 1400 kw-h. per ton of ore.

All things considered, the electric smelting of zinc seems to be a commercial possibility of the near future. The fact that the zinc can be reduced, and that the other metals of the ore can be satisfactorily recovered, have been already shown. The principal things remaining to be done are, first, to control the condensation of the zinc vapor so that a satisfactory percentage of it is condensed as metallic zinc, instead of blue powder, and second, to control the furnace operation so that the cost of replacing electrodes does

not exceed the present cost for retorts and condensers.

Iron and Steel

The electric reduction of iron is certainly no longer in the experimental stage. It is meeting the requirements in the localities where it has been introduced, and for some uses the electric furnace produces a more suitable metal than the blast-furnace. For example, electric-furnace pig iron can be made much lower in impurities than ordinary blast-furnace pig iron, which makes it much easier to convert into steel in the open-hearth furnace.

The electric iron-smelting furnace at Trollhättan has, according to a writer in *Engineering*,⁹ been modified to use round electrodes 600 mm. in diameter, and an apparatus has also been added to purify the gas by washing. The furnace used 1749 kw-h. to produce 1000 kg. of iron, an efficiency of 74.39%. The consumption of charcoal is only 35 to 45% of that required in the blast-furnace. From results secured at Trollhättan it appears that the electric furnace is subject to greater variations than a well run blast-furnace and that the sulphur content of the iron is higher.

As a result of the successful operation of the Trollhättan furnace, three other furnaces have been built in Sweden, the four using 12,000 hp.; in Norway there is one 3500-hp. furnace in operation, and three 3000-hp. furnaces are under construction; in Switzerland a 2500-hp. furnace is being built; these, with the two California furnaces, one of 2000 hp. and the other of 3000 hp., make a total of 32,000 hp. for use in the electric reduction of iron.

Lyon¹⁰ compares Scandinavian practice with the electric iron furnace with California practice. The main differences are that in California no attempt is made to secure any reduction in the stack of the furnace, there is no circulation of the furnace gases, and the limestone used is calcined outside of the furnace. Further details on the operation of the California furnaces are given by Crawford¹¹. The minimum power consumption under present working conditions is given as 2200 kw-h. per ton of pig iron. The efficiency is not quite so high as the Swedish shaft-furnaces of the same power rating, but the extension of the length of the furnace is expected to remedy this, since the end electrodes work at a lower efficiency than the electrodes in the centre of the furnace, due to the increased radiating surface.

The size of the units in use is constantly increasing. Most of the Scandinavian furnaces are rated at 3000 hp., but it is reported that the A. B. Elektrometall has completed the design of a 7500-hp. furnace. The California experiments have led to the development of a furnace rectangular in shape, with the electrodes in a straight line, and it is thought that it will be possible to increase the length of this furnace indefin-

itely, as has been done with the modern rectangular copper blast-furnace.

A good summary of the present status of the electric furnace in smelting of iron ores is given by Lyon and Keeney in their paper,¹² 'Possible Applications of the Electric Furnace to Western Metallurgy,' presented at the Denver meeting of the American Electrochemical Society in September 1913.¹³

The principal advances in the electro-metallurgy of steel are along the line of increased size of furnaces, and better control of the furnace operation, giving greater capacity and more thorough purification of the charge. An induction furnace of 25 tons capacity has recently been constructed in Germany. The electric furnace is also proposed as a holder for melted steel, giving the steel time to clear itself of gas and slag before it is cast.

The number of electric steel furnaces now in operation are as follows: Europe, 112; United States, 19. The production of electric-furnace steel is rapidly increasing in Europe, the 1912 production being about 11,000 tons more than the 1911 production. In the United States, however, the production has decreased about the same amount in the same time.

The Société le Fer¹⁴ effects the removal of the hydrogen in the production of electrolytic iron by adding to the bath Fe_2O_3 , which is reduced to FeO . Iron of high quality is obtained with a current efficiency of 95 to 98%, even with current densities as high as 1000 amp. per square metre.

Ferro-Alloys

The growth of the ferro-alloy industry in the United States has been much slower than in Europe, this country having only two plants using electric-furnace processes, compared with 25 in Europe. This makes the production of the ferro-alloys, particularly of manganese, silicon, and tungsten, of interest in this country, since the production is not sufficient to meet the demand, and large quantities are imported annually, while the growing importance of high-grade and alloy steels is making these alloys of continually increasing importance. The production of ferrochrome, ferrotitanium, and ferrovanadium is sufficient to meet the domestic demand. The principal reason for the more rapid growth in Europe is the fact that power can be obtained cheaper than in this country. Ores of chromium, tungsten, molybdenum, and vanadium are found in the western United States in sufficient quantities to make further development of ferro-alloy manufacture well worth while. Keeney¹⁵ gives the results of a series of experiments in the manufacture of the various ferro-alloys in the electric furnace. Flöge¹⁶ describes the use of an electric furnace for melting the ferro-manganese used to de-oxidize steel,

resulting in a saving of 35% of the amount required when it is added in the solid form, besides giving uniform quality of metal and saving considerable time. Bingham¹⁷ patents the production of ferrosilicon using as a raw material scrap silica bricks from the lining of open-hearth furnaces, that are partly saturated with iron.

Gold and Minor Metals

The electric furnace has not yet been applied to the working of gold or silver ores, although there are conditions under which this might be advantageous. There has recently been installed at Lluvia del Oro, Chihuahua, Mexico, a furnace for the electric smelting of the zinc precipitate from the cyanide plant and smelting ore concentrates. The bullion is shipped and the slag is re-smelted or concentrated.

The electric smelting of straight lead ores has not been attempted, largely because of the ease with which these ores can be handled in combustion furnaces.

Working in a small furnace, Stephan¹⁸ reduced from an ore containing 8.33% NiO 350 kg. of ferro-nickel, carrying 4.33% Si . The power consumption was about 2000 kw-h. per ton of ore, which could probably be reduced to about 1200 kw-h. in working.

The increased use of platinum in jewelry makes it desirable to have a small furnace capable of melting over scrap to recast into ingots. In *Brass World*¹⁹ a small 'Hellberger' furnace is described. This is a small electric furnace with a removable crucible, taking 110 or 220 volts, a special transformer cutting this down to the desired voltage. One kilogram of platinum requires 10 kw-h. for melting.

Particulars concerning some experiments made by the Gröndal-Kjellin Co., of London, in smelting tin ores in Cornwall, are contained in the *Revue Industrielle*. Pure ores yielded metal of 98% purity, and Bolivian ores containing about 50% of tin and 15% of iron gave metal of 92 to 97% purity. The latter could be further refined to a purity of 99.75% by blowing air through the molten mass. The energy consumed was 1700 kw-h. per ton, but this may be reduced to 1400 kw-h. with an efficiency of 55% by using two furnaces, one for the production of high-grade metal and the other being used for the treatment of rich slags.²⁰

Michaud and Delasson²¹ patent the electrolytic refining of tin in a SnCl_2 solution carrying some MgCl_2 and H_3BO_3 . The tin-bearing material is placed in a flat porous basket that serves as anode, and the cathode is a copper plate, from which the deposited tin is removed by scrapers. In order to keep the electrolyte saturated with tin, it is circulated through a container filled with tin scrap. The yield is 2.22 gm. of tin per ampere-hour.

Metallurgy of the California Mother Lode

By M. W. VON BERNEWITZ

A general impression exists that ore treatment along the Mother Lode is sadly behind the times. During November I visited all the operating mills from Amador City to Jackson, and must confess that I was agreeably surprised, and so far as my own observations go I consider the general impression unjustified. Relatively little has been written in recent years regarding ore treatment along the Lode and the following general resumé may therefore prove useful. Except where stated otherwise, my observations relate only to that part found in Amador county. For a complete understanding of the Mother Lode of California, I would refer the reader to the interesting articles of J. H. G. Wolf, in this journal of June 21 and 28, 1913.

The ore, which is mined from all depths to 4100 ft. on the incline, may be described as a quartz containing from 1.5 to 3% iron pyrite. It occurs mostly in graphitic slates or schists. While ore averaging as high in value as \$7 per ton is produced from one mine, the general average is said to be about \$4 per ton. Ore as low as \$3 per ton may be profitably mined and milled. The ores of Bendigo, Australia, are very similar to those of Amador county, save for the arsenic in the Bendigo sulphides. The treatment is precisely the same, only that the Mother Lode mills are more up to date.

A General Review of the Milling Practice

Both vertical and inclined shafts are found along the Lode. The angle of the latter is never very flat, and skips up to 4-ton capacity are used. Rock-crushers, mostly of the jaw type, are placed on storage bins near the shafts. A noticeable feature is the complete absence of any belt-conveyors from these bins to the mill-bins, cars holding up to 4 tons moved by man or mule power being used. While it is true that in some instances the shaft-bins are a considerable distance from those at the mills and long belt installations are expensive, yet their total absence is marked. The cars of ore at the Argonaut are weighed. Elsewhere they are merely counted and a constant weight assumed. Mill-bins are all built with sloping bottoms, and there are three types of battery frames, namely, the front knee, 'A,' and standard construction. These seem to be about equally popular. With the first named, the main drive-shaft is level with and in front of the cam-shafts, the arrangement necessitating tight belts. Ten stamps are driven by each belt, and the driving pulley is driven by a clutch. King posts and other timbers are of the regulation pattern. Feeders are of the suspended and hopper Challenge types. Mortar-boxes, stamps, and other machinery made by many well known engineering firms is found in the various mills, but the local firm of Knight & Co., of Sutter Creek,

seems to have the lead in supplying mill machinery. It also makes hoists and other surface equipment. The average weight of stamps used is probably 950 lb. There are several mills, however, where the weight is as much as 1050 lb. The quartz ore is friable, and when slate is mixed with it, the average is soft, so a light stamp with a 6-in. drop, falling 95 to 104 per minute, is sufficient to do the work. It has a capacity of four to five tons per stamp-day through a 20-mesh screen. In the new 300-ton mill for the Plymouth mine, on the same vein system, 12 miles from Jackson, heavy stamps and a two-stage system of crushing with classification is to be installed, so interesting comparisons will be possible later. Both inside and outside amalgamation is practised, but although in some mills quicksilver is fed into the mortar-boxes, there are no inside plates. There is also a wide variation in practice regarding copper plates; one plant will have only a short plate, while others have sluice plates up to 20 ft. in length. With one exception, the Original Amador, no classification whatever of pulp from the stamps is made. I was informed that it had been tried often, but without improvement in results. The pulp from each battery of five stamps is divided evenly between two or three Frue vanners. It is peculiar how the millmen in different mining centres, almost as if by agreement, find one particular concentrating table to suit conditions best here the Frue type is most favored. The only other type is the Deister, there being seven at the Original Amador. The 6-ft. Frue vanners give entire satisfaction, and they are certainly skilfully operated. They are driven at from 180 to 200 strokes per minute, and the belt travel is from 2 to 6 ft. per minute. As with all ores containing pyrite, a consid-

erable amount of fine mineral escapes with the tailing, and strenuous efforts are made to catch this by canvas plants of many kinds. For many years the tailing has been allowed to flow down the different creeks in the district, but as the farmers on the lower lands complained of drainage, arrangements are now being perfected for its disposal otherwise.

To the natural question why tailing is not cyanided along the Lode, it would be safe to say, generally, that it is doubtful whether it could be made to pay. It is true that a small plant is treating the tailing from the Bunker Hill mill, but under conditions that would not be profitable to a company. Both local and outside men have sampled and experimented on the mill residue, and intend doing so again; but results have not proved favorable. I think that the main impediment is the graphite in the slate or schist, which is crushed with the ore. In cyaniding, this mineral causes a premature precipitation of gold from solutions, which is not recoverable. It is held by Stuart Browne that it is the occluded gases in the mineral that causes the precipitation. Even so, the fact remains that the graphite, or something in it not yet determined, and which is probably not to be commercially removed, gives trouble. The proof of this may be seen at the cyanide plant of Messrs. Darrow & Fitzsimmons treating the tailing from the Bunker Hill mill, where a great deal of graphitic seum is seen floating about, and recovery was reduced very considerably lately; due, without doubt, to this mineral. It is said that greasy slates in the mines will form this seum also, and possibly may give trouble. Strange to say, the addition of caustic soda to the charges of sand in the leaching vats, greatly improves extraction. Graphite is a stable mineral, and would hardly be changed by adding this alkali, yet its addition has been beneficial. Tailing from the mills is certainly rich enough for treatment if there was no deleterious matter in it. Perhaps, however, the extreme fineness of the mineral escaping the vanners and canvas plants prevents its being caught when leached as such. The problem is interesting, and before long there will undoubtedly be further work along this line.

All the mills are situated from two to four miles from any railroad terminus and concentrate has to be hauled over rough roads for shipment to smelters. The Kennedy Mining & Milling Co. treats its concentrate by chlorination, but there would seem to be a field for a central custom plant, since the cost of treatment need not be much more than the \$2 per ton freight rate to the smelters. The concentrate contains practically gold only, and with good mechanical roasting furnaces, grinding, amalgamating, and finally cyaniding, a high extraction at reasonable cost should be made. I understand that the average extraction of gold in the mills by the present methods is 82% and the cost 50 to 55c. per ton.

Where steam is required on the surface for power, oil is used for fuel at a cost of from 90c. to \$1.25 per barrel. All the mills and small outlying plants are

motor driven, electric power from the 'Electra' hydro-electric power-station of the Pacific Gas & Electric Co., eight miles away, being supplied at \$4.50 per horsepower month. Water costs 15c. per miners inch per month; yet no attempt is made to return waste water to the mills. Probably this will be done when some of the tailing impounding systems are in operation. The stamp-mills are all well kept, which is always an important point not to be overlooked, and the labor required is small.

Fremont Mill

The Fremont mine is worked by two shafts, 1500 and 2100 ft. deep, respectively, and produces 6000 tons of ore per month. At each shaft is a crusher; one jaw crusher and one of Gates type. The broken ore is conveyed several hundred feet by mule traction to the mill-bins. The battery frame is of standard design, and suspended feeders supply ore to 40 stamps dropping 6 in., 105 times per minute. Guides made by the Globe Iron Works of Stockton, and Blanton cams are used. The mortar-boxes are from the Union Iron Works of San Francisco. A 75-hp. motor is belted to the main drive shaft, and jockey pulleys keep the cam-shaft belts tight. The stamps crush through a No. 6 slotted screen, and outside amalgamation is practised on long plates. Sixteen Frue vanners save the concentrate and are driven by a 20-hp. motor. This mill is exceptionally well kept.

The tailing from the vanners is sold on a royalty

SECTION OF A REVOLVING CANVAS CONCENTRATOR.

- (1) Central spindle gear or rope driven on footstep bearing;
- (2) Tie or stiffening rods; (3) canvas or felt sloping trays; (4) annular feed launder; (5) tailing launder; (6) spray pipes.

basis, and is treated on a revolving canvas plant. In it are two 24-ft. slowly revolving machines, with several sloping decks about 12 in. apart. The distance from the central spindle to the inner periphery of the deck, which latter is about 4 ft. wide, and divided into 4-ft. sections, is 8 ft. Pulp from the mill is fed upon these decks at the inside periphery, and thence flows across to an annular launder. The decks are either covered with canvas or felt, which catches fine mineral escaping the Frue vanners in the mill. At one side of the canvas buddle, or revolving canvas strokes, is a vertical 2-in. water-pipe, to which are fitted short 1/2-in. spray pipes,

one for each deck, manipulated by a crank in such a way that the sprays wash the fine mineral off each section as it comes to the proper point. Before that part reaches this point the pulp flow is stopped on the section before. In this particular plant, after the concentrate is washed off the machines, it is elevated to a 15-ft. machine for reconcentration, the tailing being returned again to the first 24-ft. machine. The fine concentrate is shipped to smelters. During the night this plant runs without attention, being motor driven and everything slow moving.

Bunker Hill Mill

Next along the line of the Lode is the Bunker Hill. At the shaft is a jaw-crusher and 3-ton cars are trammed by hand several hundred feet to the 40-stamp mill bins. The framing is of the 'A' type with the main drive-shaft behind the mortar-boxes, this shaft being driven by a 50-hp. Westinghouse motor. The stamps and the boxes were made by Knight & Co. of Sutter Creek and are of the usual type. Punched screens are used, and amalgamation is both in the mortars and on long plates outside. Twenty-four 6-ft. Frue vanners, three to each battery, save the concentrate, which is shipped. The pulp from the concentrating tables then flows to Darrow & Fitzsimmons cyanide plant. Here it is first of all cleared of rubbish by a revolving screen driven by a small water-wheel set in the pulp launder, the flow of the pulp turning this with ease. The pulp runs from this to cone classifiers, the underflow going to eight 12 by 16-ft. wooden leaching vats, about 80 tons being treated daily. Lime is generally used to neutralize any acidity; but on account of recent troubles, due apparently to premature precipitation by graphite, caustic soda is being tried with good results. Pulp from the canvas plant drives the distributors above the leaching vats. Cyanide solution washes are forced up through the charge or on top as desired. The total time in treating one vat is ten days, after which the residue is sluiced down the creek. The overflow from the cones goes to two 30-ft. diameter revolving machines with eight decks each, having a total of 168 canvas trays with a fall of $1\frac{3}{4}$ in. per foot, similar in operation to the one shown in the sketch. Feed is stopped two trays before the final spraying, and these are given a clean-water wash, leaving only fine clean concentrate to be sprayed off. The preliminary handling of pulp from the mill launder is to be somewhat altered in a short time, by the installation of new cones above two new 10-deck machines with 140 trays covered with asphalt-felt, painted and sanded. These machines will be centre-fed over umbrella-shaped plates, instead of being fed on the inside periphery. The mechanism will also be different, as the decks of trays will revolve independently of the central feed arrangement. Generally speaking, this new machine bids fair to be the last word for this class of work.

Concentrate washed off the present machines flows to three small Pachuca tanks, which hold 188 cu. ft. of

charge per tank, the pulp being fed down a 6-ft. hose, and clear water overflowing by an annular launder. About six tons of concentrate and fine sand is caught daily. When the vat contains the required charge, lime is added at once, then the whole is given a violent agitation with air, allowed to settle, and water siphoned off. Strong cyanide solution is then added, and agitation proceeds for eight hours and settlement for four hours, when the solution is decanted to sand filters. The treatment is simply air agitation and decantation covering a total of 72 to 80 hours. All solutions are well aerated by a pump and tower. Gold-bearing solutions are precipitated by zinc shaving in small tubs, seven rows of five each for strong, and four rows of five each for weak solutions. Barren solutions go to three 30-ton wooden sumps. In cleaning up the zinc-boxes or tubs, the zinc is washed, the sludge given a sulphuric acid treatment of 24 hours, and chlorinated by adding salt, manganese dioxide, and potassium permanganate for 48 hours. Gold is precipitated from chlorine solution by ferrous sulphate, filtered, dried, and melted; the resulting bullion is of high grade. Only a small number of men are needed at this plant, and being interested in it, they work long hours. While proving that a certain recovery can be made by cyaniding the sand and fine concentrate, it is generally believed that not much profit is realized.

Original Amador Mill

The Original Amador, opened to 700 ft. by an incline shaft, is at the edge of Amador City. One and a half-ton skips feed the jaw-crushers above the mill-bins, and the broken ore is fed to twenty 1000-lb. stamps. These drop 105 times per minute and crush 90 tons per day through a 20-mesh wire screen. The battery frame is of standard design, and the boxes and stamps were made by the Joshua Hendy Iron Works of San Francisco. A 50-hp. motor drives the main shaft behind the boxes. Both inside and outside amalgamation is practiced, the latter being on plates $4\frac{1}{2}$ by 14 ft. in area. Pulp from the plates is classified, this being the only plant along the Lode where it is done. The coarse pulp flows to four Deister tables, and the overflow from the classifier goes to another cone, the underflow from which is treated by three Deister tables. Middling from the fine tables goes to a Frue vanner running at 85 strokes per minute, and the clean

SOUTH EUREKA MILL, NEAR JACKSON.

pyrite is pumped to a tank, drained, and shipped. Classification has proved to be an advantage in this mill.

South Eureka Mill

Between Amador City and Sutter Creek are several old mills which are not working, and which have the appearance of being 'old-timers.' Farther south is the South Eureka mine, which is opened to a depth of 2700 ft. on the incline. A geared hoist driven by two 400-hp. General Electric motors coupled to a rope pulley, which drives the pinion shaft, brings the $3\frac{1}{2}$ -ton skips

atically takes a cut of the whole stream in the launder once in five minutes.

Oneida Mill

A pleasant ten minutes walk brought me to the Oneida mine, which is being developed to 2200 ft. vertical depth. Flat ropes are used on the hoist, which raises the skips to a jaw-crusher. From this the ore is trammed a considerable distance to a hydraulic elevator, which lifts the cars about 30 ft. to the mill-bins. Pressure is obtained from a water-tank on a hill nearby, while the descent of the elevator forces the water

KENNEDY MINE AND MILL AT JACKSON.

to a Knight jaw-crusher, the ore falling into a storage bin. From here it is trammed to the 80-stamp mill, built by Knight & Co. This plant is a credit to any mining company, and is certainly well maintained. The framing is of the 'A' type, and four 50-hp. Allis-Chalmers motors drive the plant in four units, there being one belt to each cam-shaft with five cams driven from the main drive-shafts. The stamps crush five tons per day through a 24-mesh, brass, wire screen. They weigh 1050 lb., and drop 102 times through $6\frac{1}{2}$ inches. Shoes last 135 and dies 60 days. Amalgamation is along the usual lines. Three Frue vanners deal with the pulp from each battery, making 48 in all. They run at 200 strokes and the belt travel is 40 in. per minute. Eight tons of concentrate is collected per day. All mill floors are hosed to a collecting tank, and this material is re-treated. Before the tailing goes to the new settling pond, it is sampled by a pipe which auto-

used to a reservoir for the mill supply. The mill has 60 stamps, but only 20 of 1000 lb. each are at work. They crush about 90 tons daily through a 24-ton cap-screen, dropping $6\frac{1}{2}$ in. 100 times per minute. Twelve 4-ft. Frue vanners complete the treatment, after which the tailing is collected in a pond close to the mill. A 100-hp. motor drives the whole plant.

Kennedy Mill

The Kennedy, about one mile from Jackson, is being actively worked to a depth of 3600 ft. vertical, and the vein has been followed to 3850 ft. I saw the stopes between 3300 and 3600 ft., getting an idea of the nature of the ore and country rock. The surface equipment includes nine return-flue oil-fired boilers, making steam for a first motion Allis-Chalmers hoist, which hauls 4-ton skips. As a large quantity of timber is used in the mine, there is a considerable quantity

stocked on the surface, and a complete sawmill is in operation. The skips dump the ore upon a grizzly, and the larger pieces are broken by a jaw-crusher. All the ore drops into a storage bin, and 5-ton cars, drawn by mules, take it to the mill-bins. There are 100 stamps crushing 13,000 to 15,000 tons per month through 20-mesh screens. The style of framing is the front knee, with the main drive-shaft level with the cam-shafts. Two 150-hp. motors each drive a small counter-shaft, this in turn driving the main-shaft by ropes. Motors are placed at each end of the plant. The cam-shafts are driven by belts from clutch pulleys. The stamps, 10 to a shaft, work in Pacific guides, and drop 100 times per minute through 6 inches. Inside and outside amalgamation is the rule, the latter being

ARGONAUT MINE AND MILL, JACKSON.

on long sluice plates. Forty Frue vanners, recovering about ten tons of concentrate daily, are driven at 180 strokes per minute, and this product is re-concentrated on two more Frue machines. Below the mill is a large plant of sloping canvas tables in four units, each being divided into 13 parts. The feed is regulated to give waves of pulp on the canvas, and at regular intervals the flow is shut off each, and the fine mineral sprayed, collected, and drained. The final tailing is run down Jackson creek, but the new scheme of disposal by four elevator wheels in series will soon be in operation.

Concentrate from the vanners and canvas plant is carted to a plant about a quarter of a mile away for local treatment. This is conducted in two oil-fired, hand-fed, and rabbled, one-hearth furnaces, the firing being intermittent. The roasted ore is raked into barrows, damped down, and shoveled into four wooden vats of 10 tons capacity each. Chlorine gas is made in the usual manner by sulphuric acid, salt, and manganese dioxide. The gas 'flows' up through the charge, having about four hours contact, regular tests being made with ammonia at a vent to see if the gas is coming through. The charge then stands about 48 hours before being washed. Gold is precipitated by ferrous sulphate in wooden vats. This is made in the plant by treating iron with sulphuric acid. The precipitate is finally dried and melted at the mine and the bullion shipped.

Argonaut Mill

The Argonaut mill is opposite the Kennedy on a steep hillside. On the incline the main shaft is down 4100 ft. It is served by an electric hoist. A 12 by 16-in. jaw crusher, of Knight & Co.'s make, breaks the ore, this then drops into a bin high above the mill. Two-ton cars, hand pushed, take the ore to the mill-bins, every other carload being weighed. The battery frame is of the front-knee style. Challenge feeders supply forty 850-lb. stamps, dropping 6½ in. 96 times per minute, the daily output being 200 tons. The screening varies, but 16 mesh is mostly used. A grading test shows the following:

| Screen. | Per cent. |
|------------------|-----------|
| On 40..... | 13.33 |
| On 60..... | 16.67 |
| On 80..... | 11.67 |
| On 100..... | 9.33 |
| On 150..... | 6.67 |
| On 200..... | 5.84 |
| On 300..... | 1.50 |
| Through 300..... | 31.67 |

This shows how extremely fine the slaty matter in the ore becomes reduced even when using so coarse a screen as 16 mesh.

The mill is driven by an 80-hp. General Electric motor. Amalgamation is mostly inside, 60% of the total gold being caught there. The apron plate is 4 by 5 ft., and the sluice plate 22 ft. long. There are sixteen 6-ft. Frue vanners, which save 3½ tons of concentrate per day. Pulp from these machines flows to a canvas buddle 30 ft. diameter, with 16 decks, divided into nine tables to a deck, each table being 4 by 5 ft. The speed of the machine is one revolution in 17 minutes. Its operation is similar to that of the one described, the fine concentrate being cleaned of barren material on a 4½-ft. vanner. The buddle saves 14 tons per month. By concentration, 15% of the gold is recovered, so the Argonaut mill has a total extraction of 85%. Further experimenting is to be done on the ore at an early date.

Zeila Mill

The Zeila mill is near Jackson, and is of an old style, and out of 40 stamps only 25 are working at present. Three and a half-ton cars drawn by a stubborn mule, transport the ore to the mill-bins, after being crushed by jaw-crusher at the shaft. The battery frame is of front-knee construction. The crushing capacity of the 800-lb. stamps varies from four to seven tons per day, as the ore consists of mixed upper and lower level material. Sixteen-mesh screens are used, and inside and outside amalgamation is the rule. Pulp flows to 16 Frue vanners, 11 of which are working, and the concentrate is shipped to smelters. The vanner tailing is sold on a royalty basis, and is treated by a 40-ft. revolving canvas machine, making one revolution in 17 minutes. It consists of four decks with thirty 4-ft. tables in a deck, which are sprayed as previously described. The mineral and fine ore caught is re-concentrated on four vanners.

Progress in Gold and Silver Ore Treatment in 1913

By ALFRED JAMES

The depression of the day has surely spread to progress in practice. One would this year have seriously contemplated the necessity of sending out a blank sheet, as an adequate summary of our progress, but for the brilliant work of Denny at Nipissing. Whether looking at crushing, classification, fine grinding, agitation, filtration, or precipitation and recovery, one is impressed by the idea that during the year we have had nothing new of note, indeed that in some respects practice has possibly become decadent, due perhaps to the remission of the efforts of men formerly interested in keeping up the level of practice at certain points. There have been but few new mills and even those have been on lines already familiar. The good work of the Consolidated Langlaagte, as shown by the extremely low cyanide costs (see official report, September 30, 1913, cyaniding cost of 27c. per ton) is perhaps counterbalanced by the extreme caution which made the staff defer the adoption of filtration in place of decantation until their recent mill, the Van Ryn Deep, and even now in the new mill they are not yet prepared to install the Nissen stamp, which proved itself so satisfactory at the City Deep. The Cam & Motor and Shamva mills are not yet started.

Generally, for the year it may be taken that exceptionally progress has been on chemical rather than on mechanical lines. In addition to the Denny aluminum preparatory process we have also the increasing use of so-called 'acid' solutions in cyanidation and the substitution, in at least one case, of aluminum-dust precipitation for zinc dust.

Agitation

Agitators widely heard of last year seem now to have disappeared. To my queries as to the position addressed to the leading exponents of advanced practice in Mexico and in South Africa, respectively, I have received strong endorsements of Jay A. Carpenter's statement in the *Mining and Scientific Press*¹ "that no one of the many less costly types of agitators has as yet proved to the general satisfaction that under varied conditions it is the equal of the Pachuca for reliability and low operating costs;" and this opinion is confirmed by the adoption of this agitator in every new African wet-crushing plant.

A reference to the valuable table on compressing given in the *Mining and Scientific Press* of October 15, 1910, will show one reason for the advantage of a tall tank over a short tank. Assuming the quantity of air to vary as the diameter of the tank and the pressure as the height, then we may take it that the same quantity of air will agitate double the quantity of material, provided the latter is charged into a tank of double height. The pressure of the air, however, would

be doubled, but to compress 10 cu. ft. of free air per minute to 15-lb. takes 0.6 hp., to 30-lb. 1 hp., to 60-lb. 1.6 hp., to 90-lb. 2 hp. It would thus appear that by using a tank sufficiently tall to require high pressure air it should be possible to agitate three times the quantity of material for twice the horse-power; but an even greater advantage of the tall tank is that the lessened number of cubic feet of air necessary for a given tonnage of pulp oxidizes or carbonates a less amount of cyanide. It was surprising to find that, whereas in New Zealand results showed a less consumption of cyanide by Brown agitator than by mechanical agitator, the saving being most marked in the agitation of heavy material such as concentrate, in America at times heavy consumptions of cyanide have been reported as due to aeration action only. In every case of such consumptions which has come to my notice investigation has proved that the quantity of air used was out of all proportion to the New Zealand standard—and it must be remembered that in the latter territory not only is slime and a mixture of crushed sand and slime agitated, but even coarse sand, tailing, and concentrate.

The Continuous Process

As to whether the continuous agitation which has proved so attractive in practice—at the East Rand four nominal 100-ton agitators agitate 1700 tons of slime per diem with an extraction of 97%—should not be modified, particularly in the case of certain ores, by the interposition of desolutionizers so that the remainder of the series of agitators may be charged with fresh solution, is a matter engaging some little attention. It may be well conceived that a Dorr thickener interposed between, say, every three agitators, may have a very useful effect in the treatment of some ores, but on the other hand engineers have been faced with just this problem since cyanidation came into being. It was a question as to how many transfers were desirable, and apparatus was invented for making transfer so cheaply that even treatment in four separate vats was economically possible; but in practice it did not prove desirable and the ultimate tendency has been to revert to single treatment in one vat only, and by means of the perfect sand feed now possible from the use of the Caldecott sand and table and cone or of mechanical classifiers, for instance as the Dorr and Ovoca, collection and treatment take place in the same vat.

A New Type

A new agitator of the year is that described by Whitman Symmes in the *Mining and Scientific Press* of July 19, 1913. The agitator is an ingenious adaptation of the multi-air-lift principle to a flat bottomed

¹May 3, 1913, p. 646.

tank, and one looks forward to receiving further accounts of the results obtained in practice from its use.

Classification

All of us have at times used cones. Many of us have passed from the use of cones to classifiers such as the Dorr. Perhaps none of us who have once used classifiers of this type have reverted to cones, and I therefore confess to some little surprise at the geographical limitation of the use of these classifiers. Is it that temperaments differ, the nature of the work differs, or that it takes a long time and the expenditure of considerable effort and money to displace practice once settled? For new mills operating under the Sunday Law in the Transvaal one would have imagined that classifiers, which could be stopped at once and started up at once, would be much more convenient than cones, which have to be cleared out and re-started, and then there is the question of labor and of work accomplished. It has been a common experience to go through a large mill and to find the Dorr, Esperanza, or Ovoca classifiers absolutely unattended and with no laborer anywhere near it. Experience with cones has been quite the reverse, and the product of the latter impresses one as containing a greater proportion of fine slime than that of the former. A metallurgist of experience, who has evolved perhaps the most perfect cone of the day, writes as follows: "The cone, on the other hand, makes large capacity possible, on account of the length of the overflow rim, and is not as sensitive to changes in the amount of feed. However, I think the best classifier, where it is important to save mill head, would, or should, combine the advantages of each (classifier and cone) type, the design to embody (a) peripheral overflow rim (b) mechanical removal of sand (c) more perfect elimination of slime by an auxiliary rising current of clear water," and he suggests that (a) and (b) be accomplished by a screw conveyor attachment to the bottom of a conical classifier, which brings us to classifiers of the well known screw type of which one sees advertisements in the technical press.

Costs

There is an increasing tendency to the publication of costs in the technical press. This makes detailed reference less necessary. During the year the Hollinger mill has undoubtedly impressed everyone as a clean equipment, cleanly run, with clean methods showing clean costs. Seldom has a property received a more beneficial advertisement than that which the methods of the Hollinger staff has secured for their operations. A reference to *The Engineering & Mining Journal* of October 18, 1913, page 739, gives the costs in very great detail and also the proportion of labor and supplies comprised in such costs. Thus we find stamping costs 18c. per ton; classification and tube-milling, 28c.; thickening, 1c.; agitation, 3c.; and filtration, 15c. Smelting and retorting (6c.) comes out to nearly as high a figure as the coarse crushing. Is it too much to expect that other concerns should give their costs as frankly as the

Hollinger? Such a course certainly creates confidence and interest. If we assume an average cost for the cyanidation of crushed pulp of 1s. 6d. (36c.) per ton, it would be interesting to receive statements from the various parts of the world where these costs are being bettered, such statements to be accompanied by a note of the quantity and nature of material treated, labor conditions and rates of pay, and other items of interest. The low cyaniding cost of 13d. (27c.) per ton at the Consolidated Langlaagte has already been referred to above. At the Goldfield Consolidated² the cost may be taken at least at 62c. per ton, not including 2c. for assaying, 7c. for precipitation, and 5c. for refining, and

THE VAN RYN DEEP MILL.

omitting the water charge altogether. At the Hollinger apparently the cost is 30c. per ton, not including 7c. for classification and precipitation and 6c. for smelting and retorting. At the Nevada Hills mill³ tube-milling is given as 29c., and the system of interrupted agitation with decantation washing appears to amount to 85c., and even so filtration comes to 18c. and discharge to 12c. It would thus appear that the interrupted method of agitation referred to above may be considerably more expensive than the direct method, and the previous decantation treatments do not apparently avail to reduce the filtration costs below the high figure shown. The government report shows that the Indian mines are working at very low figures; for example,

²*Mining and Scientific Press*, Dec. 28, 1912.

³*Eng. & Min. Jour.*, March 29, 1913, p. 646.

at Balaghát cyanidation comes to 15d. per ton treated, closely followed by the Mysore at 16 pence.

Fine Grinding

The success of the Hardinge ball mill for coarse grinding, as contrasted with the modified success of the conical mill for fine grinding, has long since caused speculation as to whether short tube-mills would not be as superior to the Hardinge for coarse crushing as the lengthened mills have shown themselves to be for fine crushing.⁴ Development has been proceeding along these lines, particularly in America, where a short tube-mill 7 ft. diameter by 10 ft. long is reported to be beating a conical mill by approximately 60%; "while it takes considerably more power it gains more than twice the tonnage." In Africa the Albu-introduced shorter 16 ft. 6 in. by 6 ft. tube-mill is now almost universally adopted in preference to the old standard 22 ft. by 5 ft. 6 in. The report from Mexico as to the results obtained by boring holes in the diameter of the tube-mill at various distances and taking samples from the effluent would be more valuable if the sizing tests had been given in full and also had the relation been established between the product at the periphery of the tube-mill and that delivered at the centre. If it were assumed that a certain proportion of the particles of pulp—taking tube-mills changed below the axis—were free to traverse unground from the intake to the exit of the tube-mill along its axis, then it would be admitted that a sample taken from the periphery did not represent the pulp at the axis or even pulp at varying distances from the axis toward the periphery. To that extent, therefore, the tests may not be reliable, but it is certain that in adopting as standard the old cement ration of 4 of length to 1 of diameter, however correct this standard may have been for use in Western Australia where fine sliming to 200 mesh was employed, such ratio could scarcely be the most economical ratio for such coarse grinding as was formerly the practice in South Africa (60 mesh) or even the 90 mesh now prevalent. The shortening of the tube-mill seems therefore a step in the right direction, as also the increase of the diameter to meet the increasing size of the particles fed, owing to the adoption of coarser mesh for the stamp screens.

For some years past I have been endeavoring to have exhaustive tests made in South Africa as to the size of particle which should be the economical limit for tube-mills of the size there installed. So far back as 1905 I was led to understand by Mr. Davidsen that 10 or 14 mesh was this economical limit. If this were true—and Mr. Davidsen's figures have proved remarkably accurate in practice—then it is obvious that the proportions for a tube-mill which should be suitable for taking a 20 or even 12-mesh product would not necessarily be economical for a 3-mesh product, much less the $\frac{1}{2}$ -in. clear aperture product recently tried at one of the latest mills on the Rand. The Rand benefits most freely by the adoption of methods introduced from the

outside. The adoption of tube-mills was worked out in Australia, in New Zealand, and even in Korea, before they were introduced to the Rand, and all the information was freely available to the Rand, just as today, when the Rand is adopting Brown agitators and Butters filters, it is adopting devices which have been worked out and proved elsewhere. At the time of the introduction of tube-mills to the Rand they were used mainly for the manufacture of cement and in gold mining for absolute fine sliming (minus 200 mesh). The results of the work of various observers were freely published⁵ for the benefit of the Rand. Surely the Rand might have published in return the results of its investigations into the problems of coarseness of feed, dimensions, charge, and other matters more particularly referred to in this review for last year and in my remarks to the Chemical Metallurgical & Mining Society of South Africa. It is for the benefit of the Rand that this information is required. But even in the matter of peripheral discharge, referred to in this review for 1908, as having given to all tests a greatly superior result to the ordinary discharge, the advantages or disadvantages have not been publicly threshed out, and it has been left to this review to suggest the only possible disadvantage yet suggested, the question of consumption of power. Strange though it may seem a wet-crushing mill which discharges either at the periphery or through the trunnion by means of elevator vanes lifting the pulp from the periphery, similar to the Abbé or Schmitt feed—these elevator vanes were provided in many of the first tube mills sent to the Rand—takes more power than a mill discharging through the trunnion in the normal fashion; and again, a mill with a discharge outlet considerably larger than the inlet takes more power, other conditions being equal, than a mill with a discharge only slightly larger than the inlet—owing doubtless to the greater proportion of pebbles rubbing idly, unlubricated by pulp. It is probable that there will yet be a development on the Rand in favor of peripheral discharge, but the increased results shown by the latter cannot be properly appreciated or discounted until one knows precisely the variation in power conditions required to produce these increased results.

Power Consumption

Apart, however, from the question of proportion of diameter to length, and even of variation in size and weight of pebbles for feeds of different coarseness, there is no doubt that the main question is that of power consumption which is now so heavy as to cause one a feeling of great uneasiness. It is true that in Australia and New Zealand, and in probably other districts where tube-mills were first introduced, mills are still operated for very low power, as a result of the adherence to the old standard number of revolutions and amount of pebble charge, but a consumption amounting to 1 hp. per ton of slimed product has to be reduced.

⁴See also Gates, *Bull. Amer. Inst. Min. Eng.*, Nov., p. 2706.

⁵See *Trans. Inst. Min. & Met.*, Vol. XIV.

Various liners and roller bearings have been put forward as a solution of the problem, at least in part, and there is evidence of remarkable savings arising from the adoption of such power-saving devices, but the publication of such a paper as that of M. G. F. Söhnlein* on 'Economical Fine Grinding Pans' arouses a keen feeling on the subject.

A Remarkable Grinding Pan

At times pans certainly appear most attractive. Some experimenter publishes results which appear to be better than those obtained in practice or which do not stand critical investigation. Mr. Söhnlein's paper is thought-compelling. His 5-ft. pan, taking say 6 hp. for only 32 revolutions per minute, gave only $2\frac{1}{2}$ tons per 24 hours. This result probably reflects more on the type of the initial experiment than on the actual capacity of the pan. When, however, the pans were made to handle 7 tons of sand in 24 hours, he was obtaining a result of course better than the initial result; but at 40 r. p. m. the work of the pan did not compare with that obtained in Australian practice, where the normal speed is 56 r. p. m. for coarse crushing and about 50 r.p.m. for fine sliming. Mr. Söhnlein, however, by means of a most careful attention to detail and the exercise of no little ability to read the indications shown by his various tests and to devise improvements accordingly, was apparently able to grind 30 tons to minus 200 mesh with his one pan for less than 7 hp. This is good work and is taken as showing a result of over $4\frac{3}{4}$ tons slimed per horse-power day. Here Mr. Söhnlein's practice differs from Australian practice, which is against the breaking down of coarse sand and the fine sliming of it in one operation. A 5-ft. Australian pan is assumed to grind 20 tons of coarse sand (say 200 holes to the square inch), but to fine slime to 200 mesh 20 tons per day two pans would be installed in parallel for breaking sand with a further pan in sequence to fine slime the product of the other two pans, or say 20 hp. in all.

When one comes, however, to look into the means by which Mr. Söhnlein achieved such extremely satisfactory results, he is met immediately from various quarters with a statement that all these methods have been tried before. In Cornwall at the tin works the investigator is shown pans made in Helston with a central feed somewhat similar to that shown by Mr. Söhnlein. From Australia he is met by the statement that the central feed was tried and discarded because the centrifugal motion was such that the feed was found to be sent from the centre between the shoes to the periphery anyhow, and therefore the central feed was unnecessary; and it was pointed out that special passages between the shoes and dies were a feature of Australian practice. Be this as it may, one is impressed by Mr. Söhnlein's work, by his methods of achieving his results, and by the fact that possibly the methods employed by him were discarded by previous operators because they were not tried in the same way. Any

methods which will give four times the pulp crushed for the same horse-power are surely deserving of the closest attention of the industry, and we shall be much disappointed if we do not hear from Mr. Söhnlein and of his pan.

A point, however, which arises from perusal of his paper is that his discharged pulp, containing nearly 50% of plus-100 product, is coarser than that met with in Australia, and that it may be that the Australian practice of sliming coarse product in a separate pan accounts for the apparent excess horse-power consumption. It is difficult to realize how, if Mr. Söhnlein slimes only 30% of his material in one passage through his pan, he is to slime the other 70% and at the same time break down the new ore coming from his mill. Thus, if we assume a feed of 38 tons of sand from the Overstrom tables, and that in one passage through only one-third of this is ground, then we are met with a return of two-thirds of this to the Dorr classifier with a consequent reject of 25 tons, or 65 tons in all to be fed to the pan, which is only capable of sliming 13 tons, so that there is a consequent return of a still greater amount to the classifier until a position of equilibrium is established resulting in a lessened fine sliming output per passage. The paper is silent on the question of these returns. It is precisely for this purpose that the extra pans are required in Western Australian practice. We hope Mr. Söhnlein will let us have a further paper, with results of monthly runs; either his daily feed to his one pan is 114 tons per diem instead of only 38, or he is figuring on one-third of 38 tons only slimed per diem with results more nearly approaching those of the Ivanhoe and other mines at Kalgoorlie.

Filtration

There must be some reason for the advertised adoption of the Oliver filter at so many mines possessing fixed submerged filters. It is not suggested that the Oliver filter is a thorough washer. It was stated in this review for 1909 that there was far too great a tendency to use the fixed submerged filter in such a way that the results obtained were merely identical with those to be obtained from settlement and decantation. One welcomed Mr. Hamilton's statement as to his own particular practice, but the remarks were made as a result of working conditions observed at various plants and it would really appear as though, in the absence of any particular incentive on the part of the advertisers of the fixed submerged filter to maintain or effect a high efficiency, users are discovering that for mere subsidence results the Oliver filter is simpler and, in spite of the results shown above at the Nevada Hills, probably cheaper. W. A. McLeod⁷ shows how the discharge of unfiltered (unwashed) pulp is prevented in Western Australia, and from Asia, from Rhodesia, and from Mexico good results—6 tons per leaf per diem—are reported from submerged vacuum-filters of rapid transfer type. It is surely a decadent proposal that for thorough washing shall be substituted a mere variation of the

**Eng. & Min. Jour.*, Sept. 27, 1913.

⁷*The Mining and Scientific Press*, September 13, 1913.

decantation process so thoroughly tried out in South Africa and in Western Australia. Even if the attractive proposal, from time to time put forward in the technical press, of the continuous use of a number of Dorr thickeners and Pachuca tanks in series be considered, it is found that the number of washing transfers is so great as to make such a process appear unprofitable when contrasted with cheap effective filtration, and certainly the statement of the Nevada Hills costs previously referred to does not help the decantation theory. As worked out for a South African project of 100 tons of 21 dwt. material, it appeared that the loss of dissolved metal in residues would be 1 dwt. per ton and in solutions $\frac{1}{2}$ dwt., or 2s. per ton; the difficulty in the case of solutions being aggravated by the impossibility of adding absolutely barren solution for the various transfers.

The experiments at Pachuca of dissolving the metals in filter-presses have been as little successful as the similar experiments carried out many years ago in Western Australia. It was then established that successful work depends on efficient solution of the valuable content of the ore prior to the introduction of the latter into filter-presses. Any additional extraction obtained by solution wash through the filter-press is regarded as an acceptable contribution toward the cost of filter-pressing but not as a serious process for the total solution of the gold in an ore.

Advocates of decantation are apt to forget the trouble and expense of handling huge quantities of material; a trouble plaintively brought to my notice from the El Oro district at the time the Hacienda San Francisco, Pachuca, introduced the simpler direct practice. Even with very expensive decantation plants worked on the huge Witwatersrand scale, my experience has been that the amount of dissolved metal lost in the residue, even on very low-grade material, is greater than the extra cost of treating that same residue in Dehne filter-presses—the most expensive form of filtration at present commonly employed.

Chemical

Reference was made at the outset to J. J. Denny's work at Nipissing in the desulphuring of silver ores at Cobalt. To those of us who since the days of Moldenhauer have worked in various ways with aluminum in our solutions and have invariably discarded the use of this metal owing to the fouling of the solutions with the much too readily formed aluminum hydrate, the statements coming over on this side and finally the description of Mr. Denny in the *Mining and Scientific Press* of September 27, 1913, caused some little incredulity; but incredulity or no incredulity, the fact remains that Mr. Denny's process is giving effective results and that it has to be taken seriously. It is true that it is stated that Mr. Denny's treatment at Cobalt effects a saving of from one to four ounces of silver per ton, depending on the amount of refractory minerals present, at a cost of, say, 1 oz. of silver or actually 54c. per ton, or the cost of roasting ores at

Kalgoorlie (see this review for 1906), and therefore as a mere substitute for roasting it may appear that there is but little to gain by the change; but the more closely one investigates Mr. Denny's discovery the more one is convinced of the advantages which may arise from its application under certain conditions. W. E. Simpson has told me the result of his immersion of some Australian telluride ore in Mr. Denny's solution apparatus, and experiments carried out by me here have confirmed the importance of Mr. Denny's discovery. Metallurgists in difficulty are invited to experiment with this new contribution to our knowledge, or, better still, to communicate with Mr. Denny at Nipissing.

With regard, however, to the use of this method in practice, as also to the use of aluminum dust in place of zinc for precipitation, we have not yet sufficient information to enable us to determine the effect in practice of the accumulation of aluminum in the works solutions. We were fortunate in the early days of cyanide in the aid of natural reactions which prevented the zinc from accumulating in solution. Unless we have some similar reaction in the case of aluminum, the difficulties arising from its use may be greater than the benefits. Mr. Denny is silent in his paper, but doubtless will give us the benefit of his experiences at an early date.

Another improvement of the year is the use of so-called 'acid' solutions in the treatment of ores which are found to foul and decompose the ordinary alkaline solutions. G. Gitsham's process has been described in 'Cyanide Practice in 1910-1913,' pp. 102-104, and reference to it will also be found in the *Journal* of the Chemical, Metallurgical & Mining Society of South Africa. At one of the great gold mines in Asia, where acid solutions have been employed, a lessening of cyanide consumption is reported for the same recovery as heretofore. Sulman and Picard point out that hydrocyanic acid is commercially impracticable as a solvent for gold, but the addition to the hydrocyanic solutions of a small quantity of ferrous or ferric sulphate, or of copper sulphate, in presence of air, renders hydrocyanic acid an effective solvent, and this is probably the explanation for the use of these 'acid' solutions on ores otherwise untreatable in view of the cyanide consumption when alkaline solutions are employed.

At Pachuca, tailing formerly treated by cyanide is now being leached for a long time with hyposulphite solution containing copper. There is an extraction of 50% of the gold, a much better extraction of the silver than formerly obtained, and in addition practically a total extraction of the mercury. Solutions are precipitated by copper pellets instead of by zinc, and the sludge is distilled. The cost is less than the cyanide treatment and the mercury is saved in addition. The volatilization process of gold recovery at the Gwalia Consolidated has been closed down. This news was not unexpected. It was recognized that Ben Howe had to deal with very serious difficulties in the recovery of volatilized gold.

Progress in the Application of Compressed Air

By ROBERT PEELE

No marked improvements or radical departures in practice are to be noted for the past year, in the production, transmission, and use, of compressed air for mining service. The field of application of compressed air power transmission, however, is continually widening in connection with the arts and manufactures, as well as in mining. In foundry work, pneumatic hammers have become indispensable for compacting large molds. This practice, which began about 1908, is now common in all foundries of any importance, and many different types of hammer are in use. The applications of compressed air have also extended in other directions, for foundries and machine-shops, as adjuncts to the main power-plant.

Progress in the use of electric drives for air-compressors has continued. It is unquestionable that, whenever electric current is obtainable at low rates, as from a central power-plant, both first cost and operating cost are reduced, as compared with steam-driven compressor plants. The installation of such plants for compressed-air hoisting engines, which began at the mines of the Miami and Anaconda companies in 1911, has given satisfactory results. Seven of the main Anaconda steam hoists were changed to compressed-air drive in 1911 and 1912, namely, at the Mountain View, High Ore, Diamond, Leonard, West Gray Rock, Tramway, and Pennsylvania shafts. During the past year the work of remodeling on the same lines the plants of all the remaining Anaconda shafts has been in progress. Ultimately, at this mine, there will be 9 main and 12 auxiliary hoists operated by compressed air.¹ Tests on the Mountain View hoist (the first to be run on the new system) showed a total mechanical efficiency, without reheating, of 36.37%; with reheating, something over 50%. This practice is likely to be followed at other properties where a number of hoists can be run from central electric and compressor plants. At the Copper Queen mine, five direct-acting main hoists, and two geared hoists have recently been converted to the use of compressed air, the old boiler plants being utilized as receivers. The air is reheated to 275° Fahrenheit.²

The increase in the use of hammer-drills has been general in this country for stopping and raising and sometimes shaft-sinking. In South Africa, also, where their introduction was at first slow, recent reports show that they are growing in favor. A number of new designs, and modifications of the older patterns, have lately been put on the market.

In connection with a new method for putting down large diameter drive pipes for foundation work, by means of the Goubert pile-driver, compressed air is

used for cleaning out the pipe. As the pipes are to be filled with concrete, the material within them must be completely removed. For this purpose, at intervals of every two or three feet, the driving is stopped, a small air-pipe is forced down inside as far as it will go, the receiver pressure run up, and the compressed air turned on. This quickly empties the pipe, and driving is resumed. On the Trans-Caucasian railways, compressed air, instead of steam, is now used for atomizing fuel oil. It avoids the formation of explosive gases in the furnace and economizes fuel consumption.³

A new high-vacuum air-pump has been invented by W. Gaede. It is of the multiple rotary type, working up to about 8000 r.p.m., at which speed a nearly complete vacuum is produced.⁴

The granulation of slag by compressed air is superseding the older method by water, and is the subject of a paper recently read by G. Juntzen before the German Metallurgical Association.

The Inspiration Consolidated Copper Co., of Arizona, has ordered six 10-ton, compound, compressed-air locomotives, together with a charging compressor of capacity sufficient for 14 locomotives, which, it is expected, will eventually be installed. The pipe-line pressure is 1000 lb.; main tank pressure, 800 lb.; initial pressure for the high-pressure cylinder, 250 lb., from which it is expanded to 50 lb. Before entering the low-pressure cylinder, the air is re-heated. It is stated that tests show that this mode of using the air gives a large increase of efficiency over the single-expansion type of locomotive. A series of tests recently made in Germany on compound compressed-air locomotives gave the following results: air preheated for both cylinders to 180°C.; length of run, from 0.62 to 1.16 miles; gross loads, 70 to 166 tons; air consumption per ton-mile, 26.3 to 32 cu. ft. for adverse grades of 0.13%. Aside from the question of relative economy of electric and compressed-air underground haulage, the latter has a distinct advantage for mines working ore-bodies of large lateral extent in which there are many secondary gangways and but few long continuous lines.

A Drill Tester

A few years ago the practice was begun of making efficiency tests on compressed-air rock-drill plants of large mines. The reasonableness and practical value of such tests have appealed more and more to progressive mine managers, and during 1913 series of tests have been made at several mines; for example, the North Star mine⁵ in California, and the Ojibway mine⁶

in Michigan. Similar work, previously inaugurated, has been continued at the Franklin zinc mine, also at the mines of the Copper Range Consolidated Co., and other properties of the Michigan copper district. A drill-testing machine has lately been patented by W. D. Paynter, of Grass Valley, California, for making shop tests. Indicator cards are taken, air consumption recorded, and the strength of blow measured for different air pressures. Defective drills are thus readily detected and held for repairs, instead of being sent underground and causing loss of time. The effects of changes of air pressure and lubricants can be conveniently investigated. The apparatus is also useful for testing new equipment or for comparing the efficiencies of drills of different makes. It is adapted to both piston and hammer drills.⁷

A novel use of compressed air, for quarrying granite at Mount Airy, North Carolina, is described in *Mines and Quarry*, July-August, 1913. The granite lies in nearly horizontal sheets, forming a low hill. A hole three or four inches in diameter by five to eight feet deep is drilled near the centre of the area to be removed. The bottom of the hole is chambered out by half a stick of dynamite. In the cavity thus formed, a small charge of powder is exploded, which starts a horizontal cleavage. This is followed by a succession of charges of increasing size, the hole being plugged each time to confine the gases, until the cleavage reaches an area of say 75 to 100 ft. radius. Finally, a pipe is cemented in the original hole by melted sulphur, and connected to the compressed-air line. Air at 70 or 80 lb. is admitted, extending the cleavage over an area of several acres, thus affording a parting to which the quarrymen work in cutting the stone into blocks.

Portable Compressors

There has been a notable increase in the use of small, portable, independent air-compressors, driven by an electric motor or gasoline engine. In either case, the entire apparatus, including an air receiver, is mounted on a low truck. An electrically-driven compressor of this type, built by the Sullivan Machinery Co., has a 10 by 10-in. cylinder, and, at 20 r.p.m., compresses 181 cu. ft. of free air to 80 lb. gauge. A circulating pump is provided for cooling the air cylinder. The over-all dimensions, including truck, are about 8 ft. long by 5 ft. wide; total weight, 7200 lb.⁸ The compressor may be driven either by chain or gearing. These little plants are useful for a variety of underground service, where power is required temporarily at a distance from the main mine plant; for example, to operate one or two rock-drills, or a small pump, or a coal pick machine. Other designs of portable compressors are made by the Ingersoll-Rand Co. and the Clayton Works of the International Steam Pump Co. The Ingersoll-Rand Co. also supplies a number of dif-

ferent sizes of small, semi-portable, belt-driven vertical compressors.

Among the new gasoline-driven portable compressors are those of the Ingersoll-Rand Co., National Brake & Electric Co., and the Sullivan Machinery Co. One type, built by the last mentioned concern, is mounted on a heavy wagon truck for surface work, such as the operation of rock drills and contractor's machinery. Its rated capacity is 95 cu. ft. of free air per minute to 90 lb. at 165 r.p.m.; or 112 cu. ft. to 100 lb. at 193 revolutions. The gasoline engine is horizontal, and of 15 to 20 horse-power.

New York Law

The New York state law governing the conditions under which labor may be employed in an atmosphere of compressed air, has recently been radically amended by the Legislature. It is printed in the *Compressed Air Magazine*, October 1913, page 6998. A well known authority on compressed air engineering has called attention to two oversights in the amended law, in that it takes no account of the temperature nor of the breathable conditions of the air as determined chiefly by the volume furnished.

New designs of multiple-port, light disk air-valves are features of some recent compressors. They have a large port area and small lift. Among them may be mentioned those of Roby & Co., Ltd., Lincoln, and Walker Bros. of Wigan, England, the Iversen 'Automatic Plate' valve, made by the Mesta Machine Co., and the Rogler-Hoerbiger valve used in the Belliss and Morcom compressors, of England. All of these are spring driven, almost noiseless, and capable of working at high speed.

In 1908 the Rand Mines, Ltd., and Eckstein & Co., controlling large groups of the Witwatersrand gold mines, determined to adopt electric drive whenever applicable and to centralize their compressed-air plant. This led to the incorporation of the Rand Mines Power Co., the capital for which was furnished by the Victoria Falls & Transvaal Power Co., Ltd. The latter Company had been previously formed to supply power to the Transvaal mines, having in view the possible installation of a hydro-electric plant at Victoria Falls, on the Zambesi river, about 700 miles north of Johannesburg. This plant is still in abeyance and both companies, operating as a single engineering undertaking, are supplying power from steam turbine electric generating sets. The following is abstracted from the *Proceedings* of the Institute of Electrical Engineers, London, March 13, 1913:

The aggregate power of the plants thus far installed, or under construction, is about 180,000 kw. (241,280 hp.), while the total power now being used by the mines on the Rand is estimated at 400,000 hp. During the past year, an additional plant has been under construction and the main transmission lines extend nearly throughout the whole fifty odd miles of actively worked reef. There are four principal power-stations and two distributing stations. At two of these points,

⁷*Mining and Scientific Press*, Aug. 2, 1913, and *Eng. & Min. Jour.*, Nov. 1, 1913.

⁸*Coll. Eng.*, Nov. 1913, p. 260.

six miles apart—Rosherville (near Germiston) and Robinson Central Deep (east of Johannesburg)—are installed compressing plants supplying air to a 14-mile main pipe system. There are now in operation 12 rotary compressors of 3500 kw. each, and three new units of 7000 kw. each are now under construction; total, 63,000 kw., which is equivalent to 84,450 horsepower.

As a basis for determining a fair rate per unit to be charged to the consumers, a number of the separate mine compressors were tested. The average over-all efficiency of six of these sample compressors was 64.1%, and a commercial unit was fixed upon equivalent to 0.641 of the quantity of air which would be compressed isothermally by the expenditure of one kilowatt-hour of electric energy. The measurement of the compressed air was an important and difficult problem. A displacement meter of large size was designed, which

gave sufficiently accurate results for a flow of air through an orifice of 0.1 in. diameter. With this master unit as a standard, a series of orifices were calibrated for testing the sample mine compressors. For measuring the air used by the individual consumers, a meter working on the principle of the Venturi tube was adopted. The coefficient for the tube was fixed by a long series of tests, and measurements are now being made with extremely small limits of error. Of the air units supplied, 95% are recorded on the consumers' meters, 3% lost in transmission, and 2% unaccounted for. The delivery pressure is 100 lb., the average pressure drop from the generating plant to the consumer being not over 6 lb. The observed delivery pressure is found to vary not more than 2% from the calculated pressure. This remarkable installation of central and distributing plant is likely to be still further extended.

The Irving Leaching Process

By L. S. AUSTIN

Joseph Irving, of Salt Lake City, has patented a process* for the leaching of oxidized and sulphide ores of copper containing gold and silver. Essentially it consists in crushing mixed carbonates, oxidized, or sulphide ores of copper to 12 or finer mesh. The crushed ore is subjected in leaching vats to the action of the mother liquor containing ferric sulphate from a prior leaching, to which has been added some sulphuric acid and common salt. The ore and solution together is mechanically agitated and heated by injecting steam. Upon conclusion of the agitation the mixture is allowed to settle. It is then drained and washed, yielding a copper-bearing solution, which is passed through a filter consisting of sand and fresh iron pyrite, and then through the precipitation vats. Recovery of the metals may be accomplished by electrolysis and by passing solution over scrap iron. The remaining solution can be regenerated for further use; it is oxidized by a steam jet which agitates it violently, bringing it in contact with air. The solution is then reinforced with sulphuric acid and salt, and is ready to be again used for a fresh charge.

It would appear that the free sulphuric acid reacting on copper carbonate would give cuprous sulphate which would decompose the salt as follows:

and the copper chloride, acting upon silver sulphide, would decompose it:

In presence of salt in the solution the silver chloride dissolves. Gold would be acted on in the same way.

*U. S. patent 1048541, December 31, 1912, *Salt Lake Mining Review*, XV, 17; *Met. & Chem. Eng.*, XI, 160.

Ferric sulphate, acting on chalcocite, changes it to copper sulphate thus:

and the resultant CuS, as well as that in the same condition in the ore, would be changed as follows:

When the ore has been leached, the resultant solution, before going to the scrap-iron boxes for precipitation, must have the ferric sulphate changed to ferrous form, otherwise the consumption of scrap iron will be largely miscarried. This is done, as already specified, by running the solution through a filter containing fresh pyrite.

This ferric is changed to ferrous sulphate and sulphuric acid is regenerated.

After the copper, gold, and silver have been precipitated the barren liquor, being agitated by a steam jet, its contained ferrous sulphate is changed to ferric sulphate.

Fig. 1 is a plan of a 50-ton mill, designed for the effective carrying out of the process along lines suggested by the long experience of the inventor in the hydrometallurgy of copper.

The ore, after coarse crushing, goes to the 100-ton storage bin *B*, whence it is fed regularly to a Hardinge mill, being crushed in the iron sulphate solution flowing from the iron sulphate storage tank. The leaching vats *E*, *E'* are alternately filled with the pulp, being at the same time agitated by a four-arm stirrer. When two-thirds full the proper quantity of sulphuric

acid is run in from the acid storage tank or acid-bearing liquor from the dilute copper sulphate storage tank *D*. When a vat has been filled with pulp, the stirrer is stopped and the contents allowed to settle. The supernatant liquor is now decanted, going to the strong liquor storage tank *J*. The pulp left in the leaching vat is drawn off to the cone-classifiers *F* and *G*. In these classification is effected by aid of a rising current of wash-water, while the underflow from both cones goes to the concentrating tables in case it contains heavy sand of value, otherwise it is wasted. From the concentrating tables the tailing, if worth while, can be pumped back to the Hardinge mill for further treatment. The overflow from the second

cone *G* goes to the pulp storage tank *H*. From this, as much of the clear liquor as possible is decanted before the remaining slime is withdrawn at the bottom to one or other of the filter-tanks *I* and *I'*. The filter-tanks have false bottoms of porous tiles which will be unaffected by the acid liquid. The filtrate from either tank is withdrawn to either of the liquor storage tanks. One of the tanks is for the stronger, the other is for the weaker solution. From these the solution is delivered in regulated flow to the electrolytic-deposition boxes *K, K, K, K*, where most of the copper is precipitated electrolytically. The partly impoverished liquor then goes to a sump-tank *L* and to the iron precipitation tanks *M, M'*, where the remaining copper is recovered by scrap iron; or the solution at *L* containing a little copper, may be sent back by a centrifugal pump to the copper sulphate storage tank *D* to be again used. The barren solution in the second sump tank *N* is also sent back by a centrifugal pump to the high level iron sulphate tank *C* and is there agitated by blowing in steam, whereby the ferrous sulphate is changed into ferric sulphate, and is then ready for use on a fresh charge. The cycle of operations for crushing, filling tank, leaching, and washing contents, and finally emptying tank, will average 48 hours.

A number of laboratory tests in 1 to 5-lb. lots have shown an extraction of copper varying from 77 to 99% and with an average of 91.4%; while several ores which had appreciable amounts of gold and silver with the copper were also found amenable; for example:

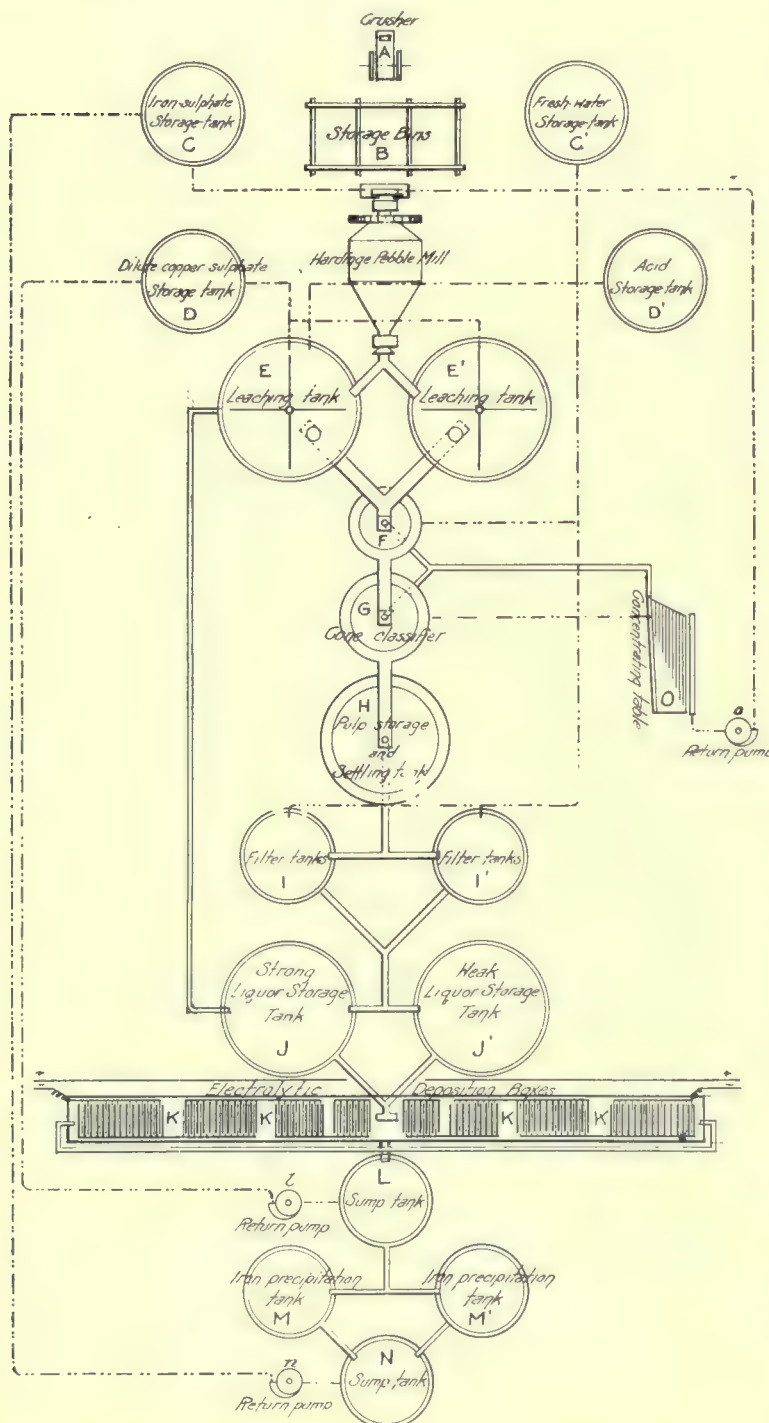

| | Gold. | Silver. | Copper. |
|--------------------------|-------|---------|---------|
| Utah ore: Original | 0.06 | 0.56 | 1.60 |
| Tailing | 0.01 | 0.09 | 0.13 |

This amounts to an extraction of 75% of the gold, 83% of the silver, and 92% of the copper.

On a larger scale, using 700 lb. of copper ore containing 1.32%, an extraction of 79% was made; on another lot of 1500 lb. containing 1% copper there was a recovery of 74%. In precipitating the copper there was consumed 1.28 lb. iron per pound of copper recovered.

On these 50-lb. lots, some Utah copper ore, containing Cu 0.81%, together with 0.145 oz. Au, and 5.06 oz. Ag per ton, gave, as the result of three tests, an average extraction of 56% of the copper, 41% of the gold, and 60% of the silver with a copper precipitate containing 68.52% copper with 1 oz. of gold and 189 oz. of silver per ton.

On an operating scale, March 1913, on some Nevada ore a charge of 23.19 tons, containing 4.65% copper, gave the following results using decantation and leaching, the ore hav-

ing been crushed in the returned barren solution; there was actually extracted by the solution 93% of the copper. Precipitation was slow because all the iron was new. There was used 1603 lb. of acid; the milling time was 9½ hours.

On another charge, 30 tons dry weight, March 1913, the ore contained 2.86% copper. The ore was crushed in the barren solution, and after settling 12 hours the supernatant solution was decanted. Acid was then added and the whole mass was stirred and allowed to settle. The decanted solution contained 1.57% copper. The total copper dissolved was 1610.66 lb., equal to a 94% extraction and 3200 lb. of acid was used. This charge contained a very large portion of copper glance (chalcocite). It is interesting to note that ores containing copper glance leach slowly.

On copper carbonates and oxides, and with acid quoted at an average price of \$25 per ton, the acid consumption would be 2c. and average treatment costs 4 to 5c. per pound of copper. On heavy sulphide ores acid consumption would be 3c. and average treatment costs 5 to 6c. per pound of copper. It is estimated that a crushing and leaching plant to treat 100 tons per day would cost \$35,000. This includes building and equipment complete. Scrap iron delivered would cost \$15 per ton. The consumption of iron is placed at not to exceed 1.5 lb. per pound of copper recovered and of acid not to exceed 2 lb. per pound of copper, and it may be considerably less than that.

Gold-Dredging in Burma

Gold-dredging in the Irrawaddy river has been actively carried on for the past eight years by the Burma Gold Dredging Co., according to an article in the *Rangoon Times* recently quoted by the *Far Eastern Review*. Starting with one small dredge, the Company has increased the magnitude of its operations until it now has five boats on the river. The dredging is entirely confined to the bed of the Irrawaddy river, for there appears to be no beach-gravel or benches containing gold. The banks of the river are high and consist of solid rock. Dredging on the river is both difficult and hazardous, although the gravel, where accessible to the dredges, is said to be easy to dig and free from large boulders. The gold occurs in an extremely finely divided condition. It is stated that about 50 miles of the inner bed contains gravel which is profitable and suitable for dredging. The gold content is low, but the average per cubic yard is not stated. During the eight years of operation, the Burma company has made a total recovery of gold valued at about £150,000, but the earnings have been insufficient to permit of the payment of dividends. It is stated that the cost of operating is approximately 4c. per cubic yard. The management has found that the native laborers are quite competent to handle the dredges after they have been trained by white dredgemen, with the result that the expert white labor has been found unnecessary.

Flotation Processes During 1913

By EDWARD WALKER

In reviewing the progress of flotation processes of concentration during the past year, the subject naturally divides itself into two parts dealing with law-suits and technology, respectively. Never was any branch of metallurgy fraught with so many disputes, both legal and personal, and to an independent journalist it is no congenial task to have to write on the subject at all. Even now the last echoes of my article appearing in your pages in January last have not died away. I shall begin by recording the legal history of the year.

The appeal of the Elmore against the New South Wales judgment was heard in October before the Judicial Committee of the Privy Council, and after the arguments were completed the litigants were notified that the case was to be re-heard in January. The reason for this step was not given, and all sorts of wild guesses have been made on the subject. The less said by me on this occasion the better. The other litigation was in the Montana court where Minerals Separation sued James M. Hyde for infringement in connection with the plant at the Butte & Superior. The judgment was against Mr. Hyde, but it did not involve the Butte & Superior company, and so did not further the collection of royalties on the ore treated. A separate action was commenced in October with the latter object in view and was decided in November. The Butte & Superior entered a different defense from Mr. Hyde, and pleaded that it used more than 1% of oil, claiming thus a distinction from the Sulman-Picard-Ballot process, which refers to comparatively minute quantities of oil. It was held that there were no new issues involved in the case, and while a preliminary injunction was refused by the Court because of the industrial disturbance that would have resulted, the Butte & Superior was put under bond pending decision of the appeal of the original case. A year ago I mentioned that J. D. Wolf was intending to bring suit for infringement of his rapid-agitation method as applied to flotation. Nothing further has been heard of this, and the inventor is apparently waiting for the result of the Elmore-Minerals Separation suit.

As regards the technology of the subject, the Minerals Separation process continues to prove its effectiveness and cheapness, and its use is extending widely. It is not necessary to give details of the many plants erected or in course of erection, but it is opportune to say that the first part of the plant at the Inspiration copper mine in Arizona was ready for operation December 1, though actual commencement of operations has been delayed owing to failure of power. Work will doubtless begin in January with a capacity of 600 tons per day. Much has been heard recently of three processes developed at Broken Hill that may be described not unjustly as modifications of the Minerals Separation process adapted for special purposes; that

is to say, they are intended for selectively separating the galena and blende in the slime. Lyster's process in use at the Zinc Corporation plant and owned by Minerals Separation consists of floating the galena and leaving the blende to sink. This is effected without acid and with a small amount of eucalyptus oil, in water at the ordinary temperature and charged with salts such as the sulphates of lime and iron. The Owen and Bradford processes aim at floating the blende, using very high temperatures, and more acid and oil. The Owen process is being installed in the Sulphide Corporation, Broken Hill South, and De Bavay's plants. The Bradford process is being worked at the Proprietary and is a modification of the Potter-Delprat process, introducing oleic acid. The variations between these three processes are, of course, largely caused by the different constitutions of the ores to be treated. The Horwood process, involving a part roast to sulphatize the galena, is in use at the Zinc Corporation mill, and its value as compared with the Owen and Bradford has yet to be tested. The Elmore vacuum process is not being used to any great extent nowadays.

The other process that has potentialities is the Murex, and probably its future will be in the treatment of carbonate copper ores. At the Whim Well, in Western Australia, excellent results are obtained, though a hitch has temporarily intervened requiring the substitution of dry crushing and dry screening instead of the wet-crushing plant. The cause of this trouble was the kaolin in the ore making a mud that would not pass the screens. The process is at work at Malines, in France, on a zinc-lead ore, and at the Grund mine, in the Harz mountains, Germany. The most recent plant built is one shipped to the Kahn copper mine in German Southwest Africa. It has a capacity of 200 tons per day and is to treat a mixed carbonate and sulphide copper ore. The plant at the Cordoba copper mine, in the south of Spain, is not giving satisfaction, and the directors are threatening to suspend its operation. This plant does not treat the whole output, but only the re-crushed jig-middling. The process was adopted on account of the large amount of calcite, which consumed the acid used by other processes. That was several years ago, and probably some modern modification of the Minerals Separation would be applicable. No doubt also some of the modern concentration tables would be of service. The dissatisfaction at Cordoba is, however, not associated entirely with the process itself; it is largely caused by the poor quality of the plant.

Application of flotation methods to treatment of copper ores made great strides in America in 1913. It is now being used from British Columbia to Chile and its applicability to Alaskan ores has been shown by test. Its importance in this connection is due to the fact that the copper ores are the ones that are now being worked upon large scale and at the same time the ones where wet-concentration is especially imperfect.

Mining Litigation—Review and Forecast

By ROBERT M. SEARLS

The year which is just passed has not been noteworthy for any number of important decisions in mining cases. Perhaps the overruling of the Yard decision by the new First Assistant Secretary of the Interior in the case of J. P. Nichols and Cy Smith before the Land Department, is entitled to the most important consideration. Although the effect of the Yard decision, as a precedent for the general interference of the Land Department in the matter of oil placer locations was largely nullified by the Act of Congress of August 24, 1912, it has remained for the present administration in the Interior Department to clear the horizon generally by flatly overruling this decision. If government lands have been illegally located or are being illegally held under the mining laws, the proper forum for determination of this fact is now admitted to be in the courts, not before the Land Department.

Only two cases of any importance involving extralateral questions reached the Appellate Courts, the Round Mountain case in Nevada and the Stewart-Ontario case in Idaho. In the first case, although the orebodies in dispute were in the extralateral segment of the vein, the case hinged on the right of the plaintiff to swing its location lines under an ambiguity in its patent so as to include a segment of defendant's extralateral sweep. The court permitted the defendant to go back of the patent and show from the record the relative rights as established by location priorities. The case is still pending on a re-hearing. The Stewart-Ontario case involved an attempt to claim an apex on the faulted edge of a vein, the court holding that no extralateral right could be predicated on such a showing as it would involve taking the right on the strike instead of on the dip of the vein. The decision also reaffirmed the rule that the end lines of the discovery vein are the end lines for all secondary veins having their apices within the claim. This case has been taken to the United States Supreme Court and is still pending.

Two interesting decisions by the Federal Courts in Wyoming and Idaho in the Duffield-Chemical Co. cases have upheld the jurisdiction of the courts to determine the character of the land involved in a suit brought on an adverse claim by lode claimants against applicants for a placer patent to the same ground, where such a determination is essential to a proper decision of the controversy. Incidentally it was held in these cases that rock phosphate is properly locatable as a lode and not as a placer deposit.

Distinction between bona fide and paper oil placer locations was made by the California Supreme Court in the case of *Smith v. Union Oil Co.* Neither plaintiff nor defendant had made an actual discovery of oil, but the junior locator was in actual possession and proceeding with due diligence to make a discovery

on the claim which the senior locator had held for 27 years without other evidence of title than a paper location. Upon such a showing the junior locator was allowed to quiet title against the senior. Work done on adjoining claims was not allowed to count as discovery work on the claim in dispute.

An interesting case arose in Utah involving the measure of damages where one of two co-tenants has extracted ore and failed to account to the other co-tenant for a share of the proceeds. In this case of *Silver King Coalition Mines Co. v. Silver King Consolidated Mining Co.*, the court held that the defrauding co-tenant was liable only for the value of the ore less the cost of mining the same, on the grounds that the taking of the ore was lawful although the detention of the proceeds might be unlawful, and that hence the lesser measure of damages should prevail.

The escape of tailing from the Arizona Copper Co.'s mill into the Gila river was perpetually enjoined by the United States Supreme Court at the suit of riparian agriculturists whose lands had been injured by such deposits. In addition to the foregoing, a few cases on the question of conflicting location boundaries and a large number of suits involving the construction of oil, gas, coal, and other mining leases have been decided during 1913.

Decisions Expected

The coming year promises to bring some important decisions terminating cases of great national interest. Chief among these are the suits brought by the United States and private locators to test the validity of patents held by the Southern Pacific Railroad Co. covering a large acreage of valuable oil lands in California. The Kennedy Extension-Argonaut case in Amador county, California, involving extralateral ownership questions, should reach a decision in the trial court and the considerable sums which have been accumulating as the output of the Argonaut mine during this litigation be released. In Arizona there is a condemnation suit pending between the Inspiration and New Keystone Copper companies, the decision of which will settle for that state the question of whether mining is a public use in view of the existing constitutional and statutory provisions. In Alaska, the new territorial mining code will doubtless be productive of litigation, especially those provisions which require \$100 worth of labor to be performed annually on each 20-acre subdivision of an association placer location even though such location may have been made prior to the enactment of the code.

Outside of the field of litigation, interest in the mining world will centre on the movement which will doubtless crystallize into congressional bills looking to an entire revision of the mining law of this country. Just what will happen it is too early to predict, but there is already enough discussion on both sides of the question to insure its presentation to Congress from all points of view, and to warrant a fair consideration of the subject at the hands of the national legislature.

Quicksilver Production and Prices

By CLIFFORD G. DENNIS

During the past year the quicksilver producers have experienced not only a decrease in price for their metal, brought about by London sales and the effect of the new tariff schedule, but have suffered with all other industries through decrease of sales and corresponding increase in stock. Quicksilver is something that consumers do not buy because it is cheap, but because they absolutely need it in their business. Consequently a decrease in price does not mean increase in sales and increase in mine operations; instead, as in the past year, it means storing what surplus accumulates and curtailing production and expense where curtailment can be exercised without dangerous disorganization. The price of the metal is regulated by the London market absolutely, the only exceptions being those brought about by the zeal of the different agencies to do business. This zeal, for the past three years, has reduced the price received by the American producers from \$3 to \$5 per flask below the price indicated by the London market.

The production for the United States is estimated at 23,000 flasks, which is below normal. That for the past ten years has averaged 25,619 flasks. The average price actually received during 1913 was \$39.25 per flask. The average price for the past ten years was \$41.83 per flask. The gross value for 1913 was \$902,750; the average gross value for the past ten years \$1,071,650. Of the 23,000 flasks produced, California furnished 18,000; Nevada, 2400; and Texas, 2600. Oregon failed to report any production, as did also Utah and Arizona.

The New Idria mine, in San Benito county, California, continued to maintain the largest production in the United States. The Guadalupe mine, in Santa Clara county, California, ranked second, and the Chisos mine, in Brewster county, Texas, third. Operations at the New Idria mine continue to demonstrate the almost inexhaustible supply of mercury ores that occur in the oldest of Coast Range formations, early Cretaceous metamorphic, and of the consistency of this belt of material that extends from Lake county in the north to San Luis Obispo in the south. At the Oceanic mine, in the latter county, operations are proceeding with very satisfactory results. Murray Innes, of San Francisco, recently purchased this property from the Oceanic Quicksilver Co. of Los Angeles. Mr. Innes reports that during the past year he has developed 300,000 tons of ore with a tenor from 8 to 10 lb. of mercury per ton, that the ore is very even in grade, that the vein is from 20 to 40 ft. wide, and that the shoot is 800 ft. long. A shaft from the present fourth level is under way, the intention being to sink to a depth of 500 ft. It will be interesting to learn what the geologic conditions are, when the shaft at the Oceanic mine penetrates the sandstone and enters the

metamorphic formation. At the Gaudalupe mine in California the furnaces have been running continuously, and it is said that developments in the mine have demonstrated that there is more ore in sight than was extracted in 1913. At New Almaden, the Quicksilver Mining Co. ceased mining in June at the time of the reorganization of the Company. Since that time the furnaces have been operated from ore gleaned from old dumps by sorting. The Company contemplates an extensive development program during 1914. This development will probably consist of exploring that territory between Mine hill, where the old mine was situated, and the El Senidor mine about $3\frac{3}{4}$ miles distant. Most of the ore mined at New Almaden for the past few years has come from the El Senidor and the possibility of more ore in this mine is most promising. At the Helen mine, in Lake county, California, production has been curtailed while extensive development was proceeding.

The Chisos mine, in Brewster county, Texas, continued to operate throughout the year. Other activities in the Texas field consisted of prospecting and development only. In Arizona, the Cinnabar Development Co., operating the old Colonial mine in west central Yuma county, failed to report any production. It was rumored that a set of retorts was to be placed at this mine to work the rich ore that was found on the lower levels. The Sunflower Cinnabar Mining Co., with headquarters at Phoenix, Arizona, has taken over a property near Cline, in Gila county, and is expected to begin the erection of a furnace immediately.

The Mercury mine at Ione, Nevada, continued to operate its furnace throughout the year. The Nevada Cinnabar Mining Co. completed the erection of a 50-ton plant on the Ione property. The plant consists of a double, four-tile, Mirabel type, Scott furnace, and eight double condensers. The plant itself is one of the best ever built, but the situation and arrangement could have been more convenient and better adapted to the delivery of the ore from the mine. The common brick for the furnace was made on the ground from a comparatively weak clay full of sharp angular bits of rhyolite, the moulding was done with a soft-mud machine; the result was a hard, square, almost perfect brick far superior to the common slop brick. The Ruby mine, situated about five miles south of Imlay in the Humboldt range, erected a battery of twelve 12-in. pipe retorts during the year and had a satisfactory run. It is proposed to erect a furnace on this property in the spring. The Nevada Quicksilver or Goldbank Quicksilver mine, situated about 40 miles south from Winnemucca, Nevada, has done considerable developing and has exposed the largest single deposit of cinnabar in the state. There is not a great deal of high-grade ore, but a large quantity of commercial ore is exposed and so situated that it can be mined at a low cost per ton. The metal occurs generally in an imperfect agglomerate. The agglomerate lies quite flat in parallel bedding, varying in thickness from a foot to four feet. These 'reefs'

of agglomerate alternate with strata of altered rhyolite varying from a few inches to several feet in width and thoroughly saturated with cinnabar. At a distance of approximately 300 to 400 ft. is a strong fissure filled with opaline material that carries a little cinnabar. The evidence of hot-water circulation is very clear and the relation of this main fissure to the ore-bearing material will prove a most interesting study as the work progresses. Upon locating the points on the map where mercury occurs in Nevada, it is interesting to note the directness of the course between them. Beginning at the Pine Forest range (reported in 1899) in the north, thence to the Ruby mine just south of Imlay, thence to the Goldbank in the East Range, thence to the Mercury and Nevada Cinnabar at Ione, thence to the several deposits about Round Mountain, Manhattan, and Belmont, thence to a deposit reported as 20 miles east of Goldfield, thence to the Fluorine district, 5 miles east from Beatty in the south, they are practically in a straight line and include 90% of the reported occurrence of the metal.

Metal Prices and Markets in 1913

SPECIAL CORRESPONDENCE FROM NEW YORK

METAL PRICES AND MARKETS IN 1913

In 1913 the metals slumped in price, apparently in line with the statement that the times call for a readjustment of the cost of raw materials. The declines were helped along, of course, by the lessening of business activity in the last four months of the year. The year was notable for the low points reached by copper stock, at home and abroad. Exports were good. Lead touched the lowest figure since February, 1912. The feature of antimony was the oversupply. Pig tin declined about 14c. in the year. Aluminum was greatly affected by the new tariff and suffered also from the slower activity of the automobile industry.

of the month having been greater by 5,302,928 lb. than that of February. The domestic consumption showed a marked increase in the month. In April there was another large decrease in stock, that on May 1 being 28,720,162 lb. less than that on April 1. The big reduction was due chiefly to a increase in deliveries of nearly 10,000,000 lb. over those of March, about 8,000,000 lb. of the increase being for export. In May the stock decreased 8,074,883 lb. leaving on hand at the end of the month 67,564,225 lb. May production ran 5,986,014 lb. over that of April, while domestic deliveries increased about 3,000,000 lb. and those for export decreased 17,608,749. In June there was a decline in production of nearly 19,500,000

GENERAL COURSE OF METAL PRICES PLOTTED FROM WEEKLY QUOTATIONS IN THE MINING AND SCIENTIFIC PRESS.

COPPER PRODUCTION AND DELIVERIES

The production in January—143,479,625 lb.—was the largest ever known for that month and resulted in an increase of 17,885,750 lb. in the domestic stock of surplus marketable copper. In February, for the first time since the preceding August, the figures of the Copper Producers' Association showed a decrease in stock. The decrease was only 896,134 lb., but it marked the turn, after which the stock continued to dwindle until October. As the table herewith shows, the low point with only 29,793,094 lb. on hand was reached October 1. Production fell off in February, but total deliveries increased 6,251,140 lb. A falling off in surplus stock was expected in March, but that it would decrease 18,032,928 lb. as it did, was a surprise and the more noteworthy because of the production

pounds as compared with May, which caused a decrease in stock of 14,659,619 lb., despite the fact that domestic consumption was about 12,600,000 under that of May and that export deliveries fell off slightly also. The lessened production was in part due to the strike at the Nichols refinery on Long Island. August 1 there was an increase in stock of 690,339 lb., domestic consumption in July having fallen off nearly 10,000,000 lb., while foreign deliveries increased 10,000,000 lb. September 1, the stock had dropped to 38,314,037 lb., a decrease of 15,280,908 lb. from that of August 1. The nearest previous low record was 44,335,004 on July 1, 1912. Production in August declined nearly 7,000,000 lb., while domestic deliveries were 14,745,609 lb. over those of July; with foreign deliveries over 5,000,000 less. The September production was 131,401,-

229 lb., about the same as that for August, but at the end of the month the stock had decreased to 29,793,094 lb., the smallest for any month since the first publication of the figures of the Copper Producers' Association about five years before, the nearest previous low stock having been that of September 1, 1913. The figures of the Copper Producers' Association coupled with those of Henry B. Merton & Co. Ltd., London, England, showed the world's visible supply on October 1, 1913, to be 41,119 tons, a reduction of 10,030 tons as compared with September 1 and the lowest supply on record. From October 1, the stock increased, gaining in the month 2,773,288 lb. Production in October increased 7,669,252 lb., and domestic deliveries increased 1,336,823 lb., while foreign fell off 4,961,802 lb. November brought a decrease of 4,982,773 lb. in production, but nevertheless an increase of 15,363,047 lb. in stock was shown December 1, because of the heavy falling off in domestic deliveries. They decreased 19,516,862 lb. from those of October and totaled but 48,656,858 lb., the lowest in any one month for nearly two years, the previous low record having been in January 1911, when about 42,000,000 lb. was delivered. Deliveries for export in November were 70,067,803 lb. or 1,944,330 lb. over those of October. Following tables show the United States production and deliveries, and the domestic surplus stock at the beginning of each month as presented by the monthly statements of the Copper Producers' Association:

| | Production. | Domestic Deliveries. | Deliveries for export. |
|------------------------|---------------|----------------------|------------------------|
| Total for 1911 | 1,431,938,338 | 709,611,943 | 754,932,733 |
| December, 1912 | 143,354,042 | 58,491,732 | 65,713,796 |
| Total for 1912 | 1,581,920,287 | 819,665,947 | 746,396,452 |
| January, 1913 | 143,479,625 | 65,210,030 | 60,383,845 |
| February | 130,948,881 | 59,676,492 | 72,168,523 |
| March | 136,251,849 | 76,585,471 | 77,699,306 |
| April | 135,333,402 | 78,158,837 | 85,894,727 |
| May | 141,319,416 | 81,108,321 | 68,285,978 |
| June | 121,860,853 | 68,452,571 | 68,067,901 |
| July | 138,074,602 | 58,904,192 | 78,480,071 |
| August | 131,632,362 | 73,649,801 | 73,263,469 |
| September | 131,401,229 | 66,836,897 | 73,085,275 |
| October | 139,070,481 | 68,173,720 | 68,123,473 |
| November | 134,087,708 | 48,656,858 | 70,067,803 |
| | | Domestic surplus. | |
| December 1, 1912 | | | 86,164,059 |
| January 1, 1913 | | | 105,312,582 |
| February 1 | | | 123,198,332 |
| March 1 | | | 122,302,198 |
| April 1 | | | 104,269,270 |
| May 1 | | | 75,549,108 |
| June 1 | | | 67,564,225 |
| July 1 | | | 52,904,606 |
| August 1 | | | 53,594,945 |
| September 1 | | | 38,314,037 |
| October 1 | | | 29,793,094 |
| November 1 | | | 32,566,382 |
| December 1 | | | 47,929,429 |

The total of copper exports from the United States in eleven months of 1913 as compiled by C. Mayer, secretary New York Metal Exchange, was 352,157 tons, against 298,491 tons in the same period of 1912. In the first 11 months of 1913 Germany took 134,585 tons as against 107,172 tons in the same period of 1912. In 12 months of 1912 total exports were 327,965 tons; in 1911, 336,801 tons; in 1910, 301,935 tons, and in 1909, 301,657 tons. Mr. Mayer figured the total importations in 10 months of 1913 by steamers and railroads, including ores, matte, and regulus reduced to fine copper, to be 152,000 tons, against 148,000 tons in the same period of 1912.

COURSE OF COPPER PRICES IN 1913

January was ushered in with the market quiet, but strong, at 17.75c. cash for Lake and 17.60c. to 17.62½c. for electrolytic.

The closing days of 1912 had seen good buying. The metal was tightly held by the large interests, but could not withstand the unfavorable showing of the Copper Producers' statement for December. With the appearance of these figures which showed an increase in stock on January 1 of 19,000,000 lb. over December 1, 1912, a decline set in which was helped along by the unsettled Balkan condition and violent fluctuations of copper abroad and by January 20, Lake was selling down to 16.25c. cash and electrolytic at 16c. Then came a turn upward and at the end of the month, 16.25c. cash was quoted for electrolytic and 16.50c. for Lake. Large sales were made in the month. Early February was unsettled and there were predictions that the price would drop to 15c. and at the end of the month, Lake was quoted at 15c. cash and electrolytic at 14.75c. The lower prices stimulated buying and one of the best movements of the year resulted. In the first few days of March a better demand from Europe started prices upward and by March 31 successive advances carried Lake to 15.37½c. cash and electrolytic to 15c. An additional cause of strength was the Copper Producers' statement showing that stock in February had fallen off nearly 900,000 lb. Unsettled political conditions abroad, the Balkan war then being in full swing, tended to restrict European buying, but toward the end of the month, the tension abroad eased up and foreign consumers came into the market strong along with domestic buyers, which caused prices to take an upward trend which they pursued throughout April. At the end of the latter month, Lake was quoted at 15.75c. cash and electrolytic at 15.62½c. The March report of the Producers' Association which showed a further reduction in stocks of 18,000,000 lb. was a strong bull influence. The buying, especially for Europe, continued good until almost the middle of April. Lake was becoming scarce and about this time the labor troubles in the Lake Superior District began to attract attention. European uneasiness caused by unsatisfactory conditions in southeastern Europe resulted in electrolytic dropping a few points in the early part of May, but it soon recovered and by May 10, 15.75c. was quoted, but it did not hold and at the end of the month electrolytic was quoted at 15.50c. and Lake at 15.75c. On a basis of 15.62½c. cash there was fair dealing in electrolytic early in May. The producers' statement for April, showing a reduction in stock of over 28,000,000 lb. greatly strengthened the market. June set in with Lake at 15.75c. cash and electrolytic at 15.25c. cash, but the month brought weakness and it closed at 15c. cash for Lake and 14.62½c. cash for electrolytic. The brass mills about this time began to note a decline in new orders. Toward the middle of June there was good buying, followed by quiet to the end of the month. Prices of brass and copper products weakened in June. The course of July was downward, though prices strengthened in the last week of the month. They dropped to 14.50c. cash for Lake and 14.12½c. cash for electrolytic (July 15) then turned upward and July 31 were 15.25c. cash for Lake and 15.12½c. cash for electrolytic. The last week of July brought activity in electrolytic, but Lake was nominal. In August the trend was upward and at the end of the month Lake was quoted at 16.12½c. cash and electrolytic at 16c. Lake copper continued hard to secure because of the strike in Michigan and tight holding of the available supply, but there was some buying of it in the second week of the month, which was checked by advancing prices. Late in August, the Lake situation began to clear up slowly. In September the range of prices was from 16.25c. to 17c. cash for Lake and 16.12½c. to 16.75c. cash for electrolytic. Prices were at their highest in the third quarter of the month, after which they declined and October began with Lake at 16.62½c. and electrolytic at 16.50c. The strength which was gained was almost entirely due to the diminishing stocks. Good buying attended the rise in prices, while Lake became harder to obtain than ever. In the latter part of October it became apparent that the big agencies were well sold up and second hands tried to force action by offerings at concessions but they aroused no inclination to buy. Prices fluctuated in a

lively way in October, but near the end of the month settled at 16.87½c. cash for Lake and 16.62½c. for electrolytic. From this time until near the end of the year there was little buying of copper, although the statistics were strong. Quotations declined steadily until 15.25c. cash for Lake and 14.62½c. for electrolytic were quoted. It had been believed that consumers would be forced to buy for December, but the hopes did not materialize and the big agencies as well as second hands came down in prices. There was some business, but not nearly as much as had been looked for. In the latter part of November it was no longer a secret that new orders for brass and copper products had fallen off sharply with the general decline in all metal lines and reductions in prices were a result. Some of the mills went on four and five day time and their stocks of copper on hand were sufficient to carry them along without the necessity of buying. In December there was little buying and December 23, Lake was 14.62½c. and electrolytic 14.37½c. cash.

The average prices paid for copper by the brass mills in the Naugatuck Valley (Waterbury average) in 1913 were as follows:

| | Cents. | | Cents. |
|----------------------|--------|-----------------|--------|
| December, 1912 | 17.75 | June | 15.37½ |
| January, 1913 | 17.00 | July | 14.75 |
| February | 15.50 | August | 15.62½ |
| March | 15.12½ | September | 15.87½ |
| April | 15.75 | October | 16.87½ |
| May | 15.87½ | November | 16.25 |

SPELTER

This metal began the year at 7.30c. New York and 7.17½c. St. Louis, and at the end of November was about 5.15c. New York and 5c. St. Louis. It dropped to 6.80c. New York in January. In that month German spelter was imported and sold at or near 7.05c. on the Atlantic seaboard. Fears as to results the new tariff might cause was an unsettling influence on the market in the greater part of the year. In February, prices dropped to 6.25c. New York and 6.10 St. Louis. In March, demand was good, the trend turned upward and prices advanced to 6.40c. New York, and 6.25c. St. Louis, but the strength did not last long and the month closed at 5.85c. New York and 5.70c. St. Louis. In April, prices declined further, demand having been satisfied, and the market in consequence, being quiet. In this month large quantities were being delivered against old contracts to both brass mills and galvanizers. In May quotations had dropped until near the end of the month they were about 5.35c. New York, and 5.20c. St. Louis, and dullness was the principal feature. In June, when quotations touched 5.10c., New York, and 4.95c. St. Louis, business was slow, but it picked up at the end of the month and the New York prices advanced to 5.30c. In early July there was good buying and in that month prices mounted to 5.60c. New York, and 5.45c. St. Louis. In August, business was fair and quotations advanced to 5.90c. New York and 5.75c. St. Louis. The advances were accelerated by strike troubles in the West and higher prices of ore. Not until about the middle of September did prices begin to decline again, but after that time they came down steadily and on September 30, the New York price was 5.60c. In September, foreign spelter was again offered but found few purchasers and this time it was said that consumers preferred the domestic metal with the qualities of which they were more familiar. October saw a continuance of the decline, and the month closed with the New York quotation at 5.40c. Steady declines and little business were the features of November and on December 1, quotations were 5.15c. New York and 5c. St. Louis. These held to December 23, up to which time business was light.

LEAD

Throughout January, February, March, and until April 22, lead quotations were 4.35c. New York and 4.20c. St. Louis. On the date named the A. S. & R. Co. advanced quotations to

4.50c. New York and 4.37½c. became the price for St. Louis. Prior to the advance the routine demand was maintained and, intermittently, good buying occurred although it was repeatedly said that uncertainty over the approaching changes in the tariff had the effect of restraining big business. Yet when the terms of the new tariff bill, so far as they pertain to lead, became more concrete, they had little effect on the market. It was pointed out that the tariff would only serve to prevent prices from soaring. The advance to 4.50c. was accompanied by the statement that the price had been too low. The 4.50c. price held until May 5, when there was a reduction to 4.35c. New York and 4.20c. St. Louis again, the reason announced for the change being that demand had slackened. At 4.35c. New York, the price was stationary through the remainder of May, June, and until July 29, when quotations went to 4.50c. New York, and 4.35c. St. Louis, again. The St. Louis price had varied 2½ points at times. In June the metal was high and going higher and fear was entertained of London coming to New York and upsetting this market. It proved, however, that the London market was bolstered up by a corner which did not hold. Meanwhile domestic buyers proceeded slowly. In early July, consumers began complaining of their new business showing a falling off, but latter in the month they bought more freely their stocks having become very small. The 4.50c. New York price announced July 29, held until August 15, when the A. S. & R. Co. advanced its New York price to 4.75c. At St. Louis 4.65c. was quoted at this time. Rumors of labor troubles in Missouri which culminated in a strike in August strengthened the situation, as did a good demand that came about the middle of August. When the strike was declared, August 15, the A. S. & R. Co. withdrew from the market for a few hours, then announced its advance to 4.75c. The price held until September 25, when independent interests came down to 4.70c. New York, and 4.55c. St. Louis. Meanwhile the aspect of the lead situation had been changed by the settlement of the strike in the latter part of August. Demand began to subside and finally came the reduction by independents. On October 1, the A. S. & R. Co., which had been feeling the underselling by other companies came down to 4.60c. New York and 4.45c. St. Louis. The competition continued and October 8, the big interest came down to 4.50c. New York and 4.35c. St. Louis again. Further cuts followed, in the anxiety to get business, and on October 16, the A. S. & R. Co. reduced its quotations again, this time to 4.35c. New York and 4.20c. St. Louis. Outside producers followed. With other metals declining on every side, lead held its own through the remainder of October and to November 26 when the A. S. & R. reduced its prices to 4.25c. New York and 4.10c. St. Louis. Business was light at the time and keenly competed for. December 2, the price came down to 4.00c. New York. Toward the end of the month greater strength developed.

ANTIMONY

In January both dealers and consumers were overloaded with antimony owing to a more or less frenzied buying on a rise late in 1912 and there was on all sides pressure to sell at about 9.75c. for Cookson's, 9.37½c. for Hallett's and 9c. for other grades. By February, Cookson's had weakened to 9.45c. The market continued lifeless through February and March brought no betterment, and some dealers were inclined to withdraw from the market rather than force sales. In April Hallett's dropped to 8.50c., and Chinese and Hungarian brands to 7.50c. Second hands, anxious to sell, offered Hallett's at 8.12½c. in April. May brought still lower prices, Cookson's being offered at 8.70c., Hallett's at 8.20c. and Chinese and Hungarian grades at 7.50c. The decline continued in June, but the market was otherwise featureless. In July the inactivity continued and prices were lower. In this month government statistics showed that there was in bonded warehouses about 4,500,000 lb. of antimony, which had been imported in anticipation of lower tariff duties. This amount approximates a

year's supply. August closed at 7.75c. for Hallett's, 8.35c. for Cookson's and 7.37½c. for other grades. Prices in September were unchanged. Toward October dealers were withdrawing from warehouse only metal which they had actually sold. After the new tariff became effective on October 4, the big supply in government custody was more freely drawn upon and the market slumped. The low quotations for October were 7.25c. for Hallett's, 7.62½c. for Cookson's, and 6.50c. for other grades. In November there was a further decline of about 12½ points for all grades, with business extremely slow. Conditions were unchanged in December.

PIG TIN

On January 2, pig tin for prompt delivery sold at 50.60c. and while it mounted to 51c. and dropped to 49.85c. in the next 30 days, the month closed at 50.15c., quotations which were partly sustained by the scarcity of spot metal. At, or near, the high prices a good business was done. Toward the end of the month the shortage was relieved by heavier importations. At the auction of 2500 tons of Banca tin in Holland January 29, the price obtained was 137¼ florins, equal to about 50c., c. i. f. New York. January deliveries totaled 3700 tons. In February prices weakened throughout the month, 49c. being touched February 3, followed by fluctuations in which declines were greater than the recoveries, until on February 28 the price was 47.55c. Business was fairly good in the early part of the month and the chief cause of the reduction in price was the decline in London prices. In February a shortage of spot supplies was again feared and stimulated buying to cover short contracts. It developed at this time that American consumers were overbought and many of them were embittered by the fact that prices began to decline as soon as they had loaded up, not in itself a new story. February deliveries were 3500 tons. In March the metal declined from 47.75c. on the third day of the month to 45.70c. on the 17th, then gradually picked up again until 47.90c. was quoted March 31. London early in the month was erratic, reflecting anxiety over the Balkan situation. Through March buying was intermittent and not extremely heavy at any time. About the middle of the month about 320 tons of Chinese tin arrived on vessels from Chinese ports which was unusual for this port. Deliveries in March reached the record breaking total of 5900 tons, the nearest previous high figures having been 5400 tons in April, 1912. April ushered in a rising market again and on the 14th of the month tin touched 50c. On April 17, 50.10c. was quoted, after which it declined gradually until April 30, when the price was 49.87½c. Foreign influence caused the rise. It was a market in which consumers had little faith and consequently they did little buying. Deliveries in April totaled 3450 tons. In May, prices hovered around the 50c. level until the middle of the month when a decline set in, and May 31 the price was 47c. As a rule business was dull throughout the month. The sale of 2500 tons of Banca, in Holland, May 28, realized 135½ florins equivalent to about 49.45c., c. i. f. New York. Deliveries in May were 3350 tons. June prices ranged between 46.60c. at the opening of the month and 42.50c. at the close, the decline being practically without a break. Excepting at intervals the market was quiet in June and speculation was evident in what buying there was. In the second week of the month 100 tons of Banca for which sale could not be made was returned to London. In the third week liquidation in tin holdings was forced in London because Vienna speculators could not obtain extensions of loans wherewith to finance their operations and this brought about lower prices. In 4 days, tin declined £12 in London. June deliveries were 3800 tons. In July prices came to 39.35c. (July 14) after which they rallied and crept up to 40.60c., at which August opened. In July consumers were using metal for which they had paid up to 48c. Now and then there was a day of good buying. The July sale of Banca in Holland, when 2500 tons were disposed of, brought 111½ florins, equal to about 40.60c. c. i. f. New York. The low price caused weakness both abroad and here.

July deliveries were 3900 tons. Throughout August tin was steady at about 41c. The lack of any considerable fluctuation was unusual. Trading was not heavy in the month, although on a few days fair buying was reported. Deliveries against old contracts were heavy. In August, 3600 tons were delivered to consumers. In September prices mounted to 43.80c., but they were more irregular than in the previous month and September 30, stood at 41c. again. Features were lacking, except that the September sale of Banca realized 116½ florins equal to about 42.30c., c. i. f. New York. September deliveries were 3100 tons. In October prices again pursued a rather even course and at no time were far above or below 40.35c., while business was light, and it was conceded generally that consumption was falling off. October deliveries were 3700 tons which exceeded all estimates for the month. In November, the downward course of prices continued, 39.25c. being touched early in the month, which closed at 39.50c. At no time in November was 40.25c. exceeded. Business was fair at times, but not satisfactory and it was apparent that consumers had plenty in stock, adding their purchases to the stock which they were enabled to carry over because of the smaller demand for their products. The November Banca sale brought an average price of 109¾ florins, equal to about 40c. c. i. f. New York. Deliveries were light, amounting to 2800 tons. With little trading, December presented few features. By December 23, the price dropped to 36.62½c.

ALUMINUM

At the beginning of 1913, the market was about 26.50c., whereas late in December it was 18.50c. to 19c. for prompt delivery domestic. Consumption was good in the early part of the year and prices went up a few points in March, 26.87½c. to 27.12½c. being quoted for prompt shipment domestic. From this month on, the course of prices was downward; the lowest of each month being approximately as follows: 26.75c. in April, 25c. in May, 23.50c. in June, 23c. in July, 21.50c. in August and September, 19.75c. in October and 18.50c. in November. In May there were especially heavy deliveries, and these led to resales and lower prices, the decline being helped along by apprehension over the then impending tariff changes, an influence which was felt until the new duties became operative. Pending the inactment of the bill there was accumulated in bonded warehouses a large quantity of the metal and this had a depressing effect upon the trade. The imports in August were 1,336,835 lb. as compared with 576,252 lb. in August, 1912. Later in the year a further depressing influence was the slower extent to which automobile manufacturers were purchasing. Throughout the year prices of foreign and domestic were close together and often on the same level. The slight difference, when there was any, was in favor of domestic. In late December, both foreign and domestic prompt metal were quoted at 18.75c. to 19c.

The Metal Markets

LOCAL METAL PRICES

San Francisco, December 31.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

| | | |
|---|------|---------|
| Antimony | 9 | — 9¾c |
| Electrolytic copper | 15 ½ | — 15¾c |
| Pig lead | 4.40 | — 5.35 |
| Quicksilver (flask) | | \$40 |
| Tin | 41 | — 42 ½c |
| Spelter | 6 ½ | — 6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7¼ to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 31.—The general tone of the market is strong and the feeling in general is optimistic. The copper market is strong and advancing and a large domestic business is reported. The lead market is also strong and the tendency is toward an advance, the sellers are holding back. The spelter market is quiet but firm. The Tennessee Copper Co. reports an estimated output for the month of 1,700,000 lb. copper and a total for the year of 13,252,000 lb. The price movements in the share market have been irregular during the greater part of the day and trading has been confined to but a few stocks. Operations are generally quiet awaiting the developments of the new year, which are looked upon as promising.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| | 1912. | 1913. | | 1912. | 1913. |
|------|-------|-------|-------|-------|-------|
| Jan. | 42.53 | 50.45 | July | 44.25 | 40.70 |

| Apr. | 43.92 | 49.00 | Oct. | 50.01 | 40.61 |
| May | 46.05 | 49.10 | Nov. | 49.92 | 39.77 |
| June | 45.76 | 45.10 | Dec. | 49.80 | 37.57 |

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the

open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Dec. 4 | Dec. 18 |
|-------------------|--------|---------|
| Dec. 4 | 40.00 | 40.00 |
| " 11 | 40.00 | 40.00 |

NEW YORK METAL MARKET REVIEW

Copper was quiet in December and prices declined. Spelter was not active, but gained strength. Lead saw much competition, and there were repeated reductions by the large interest which were followed by the independents. At the end of the month a change toward higher prices was indicated. Antimony was without feature. Pig tin dropped to the low figure of 36.62½c. for prompt and sales were light. Aluminum dropped a few points and showed but little life.

Copper was quiet from the first to December 23 and there were no indications on the latter date of any heavy business before 1914. Prices continued their course downward, the month opening with Lake at 15.12½c. and electrolytic at 14.62½c., while on December 23, Lake was 14.62½c. and electrolytic 14.27½c. European deliveries were better than the domestic. Exports to December 22 were good, totaling 24,999 tons.

Spelter prices held up in December better than did the others, quotations standing from December 1 to 23 at 5.15c. New York and 5c. St. Louis and gaining strength as the month came near its end. There were no features of special interest.

Lead prices on December 2 were reduced by the A. S. & R. Co. from 4.25c. New York to 4.10c. New York, the former price having been established on November 26. On December 9, the big interest announced a reduction to 4c. New York at which figure it stood throughout the month. The principal reason for the series of reductions was that independent companies had been steadily underselling the big company and getting most of what business there was to be had. The metal had not been on the same level before since February, 1912. At 4c. the A. S. & R. Co. took practically all of the business, but there was not much stirring. Late in the month greater strength developed in St. Louis and the price there crept up to 3.95c. In the early part of the month it was reported that the A. S. & R. Co. had ordered the closing of all its smelters in Mexico, including the Monterey smelter, employing over 2000 men. In all 7000 employees were said to be affected.

Antimony markets were glutted in December, otherwise devoid of feature. Prices were practically stationary at 7c. to 7.25c. for Hallett's, 7.40c. to 7.50c. for Cookson's and 6c. to 6.60c. for other grades.

Tin prices became lower in December until on December 23 the quotation was 36.62½c. for prompt deliveries. London was very weak toward the end of the month and the news from that city was pessimistic. On only a few days in December was there good buying. The total visible supply November 30, 1913, was 14,470 tons against 12,348 tons November 30, 1912. In the eleven months of the year there was a decrease of 4650 tons in deliveries, as compared with the same period in 1912.

Aluminum in the early days of December for both domestic and foreign delivery was quoted at 19c. The demand was poor, though the month was said to have brought an improvement to the automobile trade and consequently a better demand was expected to develop for aluminum. About the middle of the month prices, with domestic and foreign still on the same level, were 18.75c. to 19c. where they stood as the month was nearing its close.

Mineral Statistics for 1913

South Dakota mines produced gold worth \$7,200,000 in 1913, against \$7,891,370 in the previous year. Silver output fell from 206,460 to 164,800 oz. A small quantity of lead and copper was produced, according to Charles W. Henderson, of the U. S. Geological Survey.

Michigan copper mines produced 105,000,000 lb. of metal, or at the rate of 210,000,000 lb. per year, during the first half of 1913; but on account of the miners' strike, which began on July 23 and is still partly on, the year's output will be only about 145,000,000 lb., according to R. H. Maurer. The average price received for copper was 15.5c. per pound, making the gross value of \$22,500,000. Nine companies distributed \$8,344,788 in dividends during the term. The principal producers in 1913 were as follows: Calumet & Hecla, 53,420,000 lb.; Osceola, 11,686,000 lb.; Champion, 11,448,000 lb.; Quincy, 10,894,800 lb.; Ahmeek, 9,100,000 lb.; Baltic, 8,686,000 lb.; and Mohawk, 5,369,000 pounds.

New Mexico made increases in its mineral production during 1913, according to Charles W. Henderson, of the U. S. Geological Survey. The output of gold showed an increase of \$100,000 over the \$784,446 in 1912; that of silver, an increase of 100,000 oz. over the production of 1,536,701 oz. in 1912; lead, a decrease of 800,000 lb. from the yield of 5,494,018 lb. in 1912; copper, an increase of 20,000,000 lb. over the yield of 34,030,964 lb. in 1912; and zinc (figured as spelter or zinc in zinc oxide), an increase of 8,000,000 lb. over the output of 13,566,637 lb. in 1912. Despite lower average yearly prices for copper and zinc, the total value of the output was \$11,620,000, an increase for 1913 of over \$3,000,000.

Alaskan mines produced \$18,900,000 in minerals during 1913, according to Alfred H. Brooks, of the U. S. Geological Survey. The value of the gold output is estimated at \$15,450,000; that of 1912 was \$17,145,951. There was a marked decrease in copper production, that of 1913 being estimated to have been 19,700,000 lb., valued at about \$3,014,000, while that of 1912 was 29,230,491 lb., valued at \$4,823,031. The silver output is largely a by-product of gold and copper mining, and showed a decrease in value from \$316,839 in 1912 to about \$220,000 in 1913. Other minerals, including marble, gypsum, tin, etc., are estimated to have been produced to the value of \$220,000, or about the same as that of 1912.

California's mineral production during 1913 was valued at over \$95,600,000, according to the State Mining Bureau. This is an increase of \$4,000,000 compared with the previous year. The petroleum output was approximately 93,000,000 bbl., valued at \$43,500,000, increases of 3,500,000 bbl. and \$1,500,000 respectively. Deep mining, dredging and higher operating efficiency keeps up the gold yield to about \$20,000,000 per annum. There have been few changes in the copper mines, whose metal was worth about \$5,500,000. The cement output increased in value by \$2,000,000 to \$8,000,000. Crushed rock and granite production was \$6,000,000; brick, \$3,000,000; natural gas, \$1,250,000; borax, \$1,000,000; silver, \$800,000; and quicksilver, \$750,000. The minor mineral products showed normal activity and growth.

Coal production of the United States in 1913 was between 565,000,000 and 575,000,000 short tons, against 534,466,580 in 1912, according to the U. S. Geological Survey. Of the increase, about 4,500,000 tons was from the anthracite mines. There were a few labor disturbances in 1913, but they were local in extent and effect. The most pronounced labor disaffection was in Colorado, where a general strike was called about the middle of September, and coal production in that state during the last quarter of the year was but little more than 50% of normal. There was general complaint, particularly in the Eastern states, of shortage of labor and inability on the part of the operators to keep their mines working at full capacity. This was probably the reason for less than the usual complaint of the inadequate or insufficient transportation service. Coal-mining, like all other industries in the Ohio Valley states, was seriously interfered with by the floods in that region during the spring of 1913.

ERRATA

Referring to the description of the Irving process on page 77, Mr. Austin adds that the ferrous sulphate may be regarded as being changed to ferric sulphate according to equation

He corrects the analysis of original ore on page 78 to read: gold, 0.04%; copper, 1.63.

EDITORIAL

SANTA DOMINGO goldfields have attracted attention from time to time, and there have been many tales of riches to be found there by dredging. Mr. Henry F. Le Fevre has recently returned from an eight months' investigation of the country and permits us to quote him to the effect that there are no gold placers there suitable for dredging.

GOVERNMENT aid to prospectors by the Commonwealth government of Australia, which controls the Northern Territory, an area of 523,620 square miles, goes to lengths unknown in the United States. The government is erecting a five-stamp mill for the benefit of prospectors in the Maranboy tinfield. The erection and operation of government mills in Western Australia and Victoria has, on the whole, been a great aid in stimulating prospecting and developing new districts. Whether such means are either necessary or advisable elsewhere is less certain.

STATISTICS are interesting as approximations showing the general trend of metal production, and when estimates are presented that the calamine production of the Joplin district for the year 1913 was 40,346,251 pounds, valued at \$491,243, such figures cannot be claimed as being exact to the last digit. In the current issue we present the well known production statistics of Mr. Otto Ruhl, of Joplin, and in the Special Correspondence columns will be found figures covering the same district, compiled by our Joplin correspondent. While differing somewhat, the totals show a decided activity in the mining of the lead and zinc deposits of this district.

ARBITRATION as a means of preventing industrial troubles has not been entirely successful. A commission in New South Wales, Australia, has recently investigated the operation of that state's industrial laws covering a period of twelve years. The object of arbitration is to stop strikes and lockouts, but the Commission found that the strike is still used by labor unions. Threats of strikes are indeed more frequent than ever, and it seems that agreements by peaceful methods, such as arbitration, are still far from universal. During the nine months that ended on December 1, 1913, there have been 148 disputes in the Commonwealth, involving 41,737 employees. The number of working days lost was 529,642, and the loss in wages \$1,110,000.

FROM Malaguit in Paracale, Philippine Islands, comes the news that the village churchyard has been located as a most promising piece of placer ground and negotiations are afoot for mining it. While the churchyard has generally been consecrated to other purposes than the dredge, gold is where you find it, and who knows but what other *padres* might well turn prospectors.

AS an undesirable citizen, Charles H. Moyer, president of the Western Federation of Miners, has been forcibly deported from Calumet by the 'Citizens Alliance.' This action on the part of the 'Alliance' should meet with the approval of both strikers and operators as little good could be expected from the efforts of one so ill-reputed in the district as the present president of the Western Federation of Miners.

MEMBERS of the American Institute of Mining Engineers residing in northern and central California will meet at the Engineers' Club, in the Sutter hotel, of San Francisco, on the evening of January 12, to act upon the report of the Committee on Organization. Preceding the meeting a dinner will be served at 6:30. The subject for consideration is one of particular interest to the local engineers, and an interesting meeting is anticipated.

FURTHER argument to the effect that the mining law needs revision in more than incidental particulars is advanced on another page by Mr. Grafton Mason, who has most courteously answered our Macedonian cry for help. His arguments are not only sound in themselves, but coming as they do from one who as attorney for the land department of the Northern Pacific railroad, has seen much of the practical application of the mining law, they are entitled to consideration even from those who affect to believe that as to law no opinion is final save that of a lawyer.

FRANKNESS in discussing the situation is not easy when the grade of ore is going down. We have frequently commended the full and frequent statements given out by the Goldfield Consolidated Mines Company, and are sure that our readers will read with interest the following from a speech made by Mr. Albert Burch at a recent public dinner held at Goldfield to inaugurate a movement designed to make that city a more livable place. "So far as the Goldfield Consolidated is concerned, everyone knows that the cream has been skimmed and that we are now doing our best to subsist on skimmed milk; but at that we are doing fairly well. It can probably never be the profit-earner that it once was, nor can its present scale of operations be continued indefinitely; but on some basis the Goldfield Consolidated will be running for several years yet. We are now working a low-grade mine, and in order to make it pay we do not plan to reduce wages; nor to ask any man to break his back doing an unusual day's work; but we do ask him, if he is

our friend, to bend his back to pick up a dollar's worth of drill steel if he sees it being buried in the muck, and in any other way that he can, use his brains as well as his hands to help stop leaks." We trust that the appeal made by Mr. Burch will evoke the answer it deserves, and we hope with him that the great mine may run for many years yet.

INCOME TAX questions have been worrying officials of a good many American mining companies. Not that they are so excessively wealthy, but because of the difficulty of determining depreciation in the case of a wasting asset, such as ore in the ground. Many have been puzzled by the decision of the Supreme Court in the case of Stratton's Independence, Limited. The matter is really very simple. Mining companies will be allowed a depreciation charge of 5 per cent on their gross output, and all other possibilities are swept away. This covers the past as well as the future, and opens the way to corresponding rebates and additional collections where any other basis was used in figuring.

The Secretary and the West

The report of Mr. Franklin K. Lane, as Secretary of the Interior, for the fiscal year that ended June 30 last, was made public Christmas eve. It is a straightforward readable brief, rather than the usual dry and formal departmental document. The Secretary has had the good sense to concentrate his attention upon one of the groups of questions now before his Department, and he has presented his recommendations and the argument for them so simply, as to increase greatly the chances for securing favorable Congressional action. Many phases of the problem of further disposition of the public lands, which is what chiefly concerns the Secretary, have been the cause of acute and acrid controversy. A number are even now bitter fighting ground, and yet it is fair to say that already differences of opinion are disappearing, and there is undoubtedly a sufficient agreement as to policy to warrant Congress settling at least a few of the many vexed questions. We believe that Mr. Lane is absolutely right when he says, and the italics are his, "The West no longer urges a return to the hazards of the 'land is land' policy. *But it does ask action.*" We sincerely hope that enough of the spirit of fair compromise may obtain at Washington this winter to permit determination of at least the more pressing matters.

Speaking in general terms, the Secretary favors a leasing system for the coal lands, not only of Alaska but of the rest of the United States, and for the oil, phosphate, and potash lands. Further than that he does not go, and in this we believe him wise. What may be proper as to further disposition of other mineral lands, no one can certainly say at this time, but as regards coal, oil, phosphate, and potash lands, there is sufficient knowledge to permit intelligent action. Our own views regarding this are too well known to

require lengthy re-statement. While not prepared to endorse every detail of the Secretary's proposed form of lease, we heartily favor the general plan, and we have no fear that any bill which gets past Congress will not be sufficiently liberal. In later numbers we shall speak of particular proposals.

Another of the recommendations made by the Secretary is that the various activities of the United States Government in Alaska be placed under the charge of a single board or commission and that this board be given large freedom of action. As he truly says, "there can be no satisfactory administration of land laws, or any other laws, at a distance of 5000 miles from the point of action. The eye that sees the need should be near the voice that gives the order." It will be remembered that Mr. Taft, when president, favored a commission form of government for Alaska and that his proposal raised a storm of dissent. Since then an elective government has been constituted for the Territory and to it has been delegated the local political power. As we understand Mr. Lane's suggestion, what is now proposed is a Board of Directors to manage the property in Alaska that belongs to the United States. There is an important difference, and, while there would seem to be room for much friction between such a board and the local Legislature, the proposal merits careful consideration. Certainly there is need for bringing the administration closer to the local needs of the people, and, without pretending any great sympathy for the 'black bear which is in the care of one department while the brown bear is in another,' we are quite prepared to agree that the organization of administration in Alaska could be greatly improved.

As a whole, the report is a plea for the West; a demand that means be found, without undue sacrifice of national interests, to permit the continuance of the great work of building there homes for the people of the Nation. It is written by a man who honors and loves the West, and it rings true.

Mill Construction and Operations

In 1913 no country was especially conspicuous in the construction of new plants. In the United States, several interesting mills began work and others are well on toward completion. During October, the Commonwealth mill, at Pearce, Arizona, started work. This mill consists of 30 heavy stamps, Hardinge mills, Pachuca agitators, and Oliver filters, and has a capacity of 350 tons per day. Interesting work is being done at the Tom Reed, Gold Road, and Vulture mills, and in Texas the Presidio Mining Company has converted its pan-amalgamation mill to cyanide with a gratifying increase in capacity. In California there are four all-sliming plants, the latest being the Globe 20-stamp mill at Dedrick, Trinity county, and in a few months a 300-ton mill will be erected at the Plymouth mine, California, embodying the best Mother Lode practice together with several new features. In the meantime,

the nine mills containing 400 stamps dropping on ore in Amador county are doing satisfactory work, as described in the last issue, and elsewhere along the lode there were few changes. Small stamp-mills and cyanide plants in Oregon have continued in operation. At Fairbanks, in Alaska, 16 small mills are in operation, and at Juneau proposals for new mills to treat ore worth only \$1.50 per ton are interesting in that stamps and rolls will be tested side by side. The work here has been described for our readers by Mr. F. W. Bradley and Mr. Grant Tod. The current year should see the first units in operation.

In Nevada a 300-ton mill, containing some novel features, is under construction for the Buckhorn company. There will be no stamps, but crushers, rolls, Hardinge and tube-mills, Akins classifiers, agitators, and Oliver filters. The ore is clayey and crushes easily. At Aurora, in the same state, a large stamp-mill is being erected for the Aurora Consolidated Mining Company. In Nevada the Goldfield Consolidated treated its 950 tons per day, with the usual good results. The seven mills at Tonopah continued literally to pour out silver bullion, the production being nearly 35 tons per month. More stamps are being added to the West End mill. In Colorado the Stratton's Independence, Portland, Camp Bird, Tomboy, and many small plants have been improved and were in continuous operation. In South Dakota the Homestake company added 20 to its existing complement of 1000 stamps; the Wasp No. 2 treated ore as cheaply as ever, although circumstances prevented its operation during the full time.

At Porcupine, in Ontario, Canada, both the Dome and Hollinger mills are being enlarged. Several plants for treating gold-bearing ores have begun work in adjoining districts. At Cobalt the Northern Customs 40-stamp mill is being duplicated; the McKinley-Darragh extensions were finished; and the Nipissing high and low-grade mills continued their highly interesting work, the refinery output being about 17 tons of silver per month. Canadian authorities are now experimenting with the object of saving the cobalt from the ores of the district. Two valuable contributions to metallurgical knowledge came from the Nipissing mills: desulphurizing of the ores by aluminum, described by Mr. J. J. Denny in our issue of September 27, and precipitation of silver from cyanide solutions on aluminum dust.

Although Mexico has been in the throes of a revolution through the year, and many mining men have temporarily left the country, the mills at El Oro, Pachuca, and Guanajuato have worked without interference. Parral has had a troublesome year, and at present little is being done there. In Jalisco, El Favor plant is being enlarged, and mills of big capacity are under construction at the Cinco Minas and San Pedro Analeo mines, also at the San Martin in Oaxaca, and a 500-ton concentrator at the Teziutlan Copper Co. in Puebla. La Blanca mill, at Pachuca, Hidalgo, is being enlarged

and the agitation system altered. During the past financial year the Santa Gertrudis mill treated 263,554 tons of ore yielding 21,800 ounces of gold and 4,243,000 ounces of silver. Improvements have been made to the El Tigre mill, which treats a complex ore under numerous difficulties. Experiments with the manganese-silver ores of Jalisco are still under way. In Honduras the Rosario, in Costa Rica the Abangarez, in San Salvador the Butters Salvador, and in Brazil the St. John del Rey mills have been in continuous operation.

The Indian group of gold mines at Kolar increased its output slightly, and improvements are being made at several plants, notably in slime treatment. There were apparently no important developments in the mills of West Africa. Rhodesia has been of interest on account of the new mills under construction, or about to start work, these being the Shamva, Cam & Motor, Falcon, Antelope, Bell, Kimberley Reef, and New Found Out. Antimony has been one of the main sources of trouble in gold recovery in this country, and it will be interesting to watch results from the Cam & Motor plant where the practice includes dry-crushing in Krupp ball-mills, roasting in Edwards furnaces, leaching sand, and filtering the slime. It has been designed from the best practice at Kalgoorlie, and has a capacity of 15,000 tons per month. On the Rand, an average of 9982 stamps and 287 tube-mills have been at work crushing 2,100,000 tons of ore per month. There have been several enlargements of plant in additional stamps and tube-mills, also three new Butters filter-plants at the Randfontein Central, Van Ryn Deep, and Geduld, with daily capacities of 1500, 900, and 500 tons, respectively.

The Oriental Consolidated stamp-mills and cyanide plants in Korea have operated continuously, and crushed an average of 25,000 tons per month. The gold and silver mills in Japan have run their usual even course. In Sumatra, Redjang Lebong and Ketahoen mills treated the gold and silver ores according to their customary methods, there being no changes of importance. Going south to Australia, a new cyanide plant was erected at the Scottish Gympie mine in Queensland. This is interesting, as at Gympie there is a large amount of graphitic slate, and, like the Mother Lode of California, there has been trouble from this mineral causing premature precipitation of gold. The ore is also low grade, and care is necessary in all departments. In New South Wales, there have been improvements to the equipment at the Mount Boppy stamp-mill and cyanide plant, which treats 6000 tons per month. From the Cassilis mine in Victoria a very refractory ore is extracted, and after several years' experiments a new treatment plant, consisting of stamping, concentration, cyanidation of pulp, and roasting and other treatment of the concentrate, is soon to be completed. At Kalgoorlie, Western Australia, the dry and wet processes for treating sulphotelluride ores gave their usual satisfactory results,

and profits were made at the Perseverance and South Kalgurli from ore worth from \$5 to \$6 per ton. In this journal of September 13, Mr. A. W. MacLeod discussed the metallurgical tendencies in the state. While the development of oil-engines has expanded in other countries, the great advance made in the use of suction-gas plants in Australia, especially in the western states, has surpassed the progress made elsewhere. Grinding pans are still much in favor. Two plants have been built wherein the sand is first removed from the pulp by cones, the slime being thickened, and the sand, after being continuously agitated, rejoins the slime, both being then treated in the one vacuum-filtration plant. The Sons of Gwalia mill, 13,000-ton capacity, was remodeled; the Queen of the Hills mill, of Holman pneumatic stamps, is doing excellent work; as is the Bullfinch stamp-mill and vacuum-filtration plant. One of the most interesting mills, the success of which was doubtful at the end of 1912, was that at the Victorious mine, 40 miles from Kalgoorlie. Four Huntington mills, two pans, an agitation plant, and three Ridgway reciprocating filters treated 95,640 tons of ore in 12 months to September 1913. This ore averaged \$5.26 per ton, and the profit totaled \$173,000. The failure of the Howe volatilization process, as described in this journal of October 4, 1913, was unfortunate. As a result, two mines with large ore reserves are now shut down indefinitely. After a serious decline of the state's gold output since 1903, the past year in Western Australia has shown a considerable increase.

In New Zealand, the Grand Junction at Waihi is adding 20 to its existing 40 stamps; the Waihi company only operated its 200-stamp mill, treating 14,600 tons, yielding \$120,000 per month; at Karangahake, the Talisman continued treating its high-grade silver-gold ore, the average yields of late being 4300 tons returning \$106,000. Recovering the old tailing from the river 6 to 15 miles below the Karangahake and Waihi districts, and treating it by tube-milling, agitation, and vacuum-filtration continued with interesting success at the Waihi-Paeroa Gold Extraction plant. To date a total of 219,700 tons of tailing has yielded gold and silver worth \$340,000.

In connection with new processes, it may be said that attempts to use the Clancy system of regeneration of solutions have stopped at Cripple Creek. There is an increasing interest in the electrolysis of solutions. The new process of precipitating gold on zinc wafers does not seem to have met with success, as at Waihi and on the Rand results were not satisfactory. The litigation of the year included the Moore-Butters vacuum-filtration dispute; the Brown system of crushing in cyanide solution and concentration *versus* the Tonopah Mining Company; and the London & Hamburg Gold Recovery Company *versus* the Golden Horse-Shoe Estates Company, in connection with the bromocyanide process, and trial of issues regarding flotation as discussed elsewhere. All of these subjects received extended reference in this journal from time to time.

Gold Dredging in the United States

By CHARLES JANIN

California

Figures of dredge production in 1913 are not available as yet but are not likely to vary greatly from those of 1912 when the production of gold won from dredging operations in California was \$7,429,951; this was a decrease of \$236,506 compared to 1911. As pointed out in my review of last year, the production of gold from dredging in this state reached its zenith in 1911 with \$7,666,461, and a gradual decrease may be expected. A number of dredges, notably in the Oroville district, have exhausted, or nearly exhausted, the ground for

months out of commission, have been working steadily, and the yardage results will closely approximate those of 1912. No. 13 dredge, built in 1912, has averaged about 250,000 yd. per month from deep ground, and one month had an output of 310,000 yd. While this yardage does not equal that of the Idaho dredge, mentioned elsewhere, considering the difference in the ground handled, it marks without question just as good work. No. 14, the new steel dredge being built for this Company, and an excellent boat, began work late in December. Some delay was experienced in getting

YUBA NO. 14, THE LATEST ALL-STEEL GOLD-DREDGE.

which they were built, and, except in a few instances where the machinery from these boats can be profitably transported and used on other areas, the boats will be dismantled and the equipment used for repairs.

The most successful dredging enterprise in the state and in the world for that matter, is that of the Yuba Consolidated Gold Fields in Yuba county. With 11 dredges operating part of the time until No. 2 was dismantled, the profits from dredging operations for the year that ended on February 28, 1913, were \$1,640,848 from 164.8 acres. The depth varied from shallow ground dug by No. 9 in working to new ground, to ground 70 feet deep handled by some of the other dredges. The average amount recovered was practically the same as the year previous, 16.78c. per cu. yd., but the working cost was 5.34c. or an increase of 0.67c. per yard. The results of operations for 1913 are not yet available, but the 10 dredges of the Company, with the exception of No. 5, which sank July 31 and was two

steel shipments from the East, or the dredge would have been completed sooner. A matter of some interest to the general reader, but of more importance to those acutely concerned, is the fact that the Yuba Consolidated has distributed over \$8,000,000 in dividends among its shareholders; no phantom profits there.

The Natomas Consolidated operates 10 dredges in Sacramento county and 3 in Butte. The Company had a fair year as far as its dredging operations were concerned, though net profits fell somewhat short of estimates. The dredges handled during 1912 a total of 22,155,162 cu. yd. with an average recovery of 9.12c., and an operating cost of 4.46c. per cu. yd. The net result from dredging operations for the year was \$1,031,804. For the eight months that ended August 31, 1913, the net result from dredging was a little in excess of \$791,000, and it is expected that a total approximating nearly 24,000,000 yd. will be handled during the year. During 1913 dredge No. 7 was entirely reconstructed.

¹Nearly worked out its ground.²Indiana dredge to go to Michigan Bar, Sacramento county. Pacific No. 1 was moved to Auburn, Placer county.³Yuba 14 started December 18.⁴Three dredges in Calaveras county short of water during the fall.⁵Total approximate yardage, Shasta, Placer, Trinity, Siskiyou, and Merced counties, 3,500,000.*Table prepared by Mr. Janin for use in the *Mining and Scientific Press*, January 1913, revised by M. W. von Bernewitz.

with new steel hull, and re-commissioned in Blue Ravine May 12. No. 5, which sank June 8, was uprighted and ready for repairs early in July. Natomas No. 2 had a narrow escape from sinking July 3, but a bad leak was stopped by promptly putting cement between the outer and inner walls of the hull. Recent work by the Natomas dredges is described in the *Mining and Scientific Press* of December 27. The other operations of this Company have not attained the success contemplated, and it is undergoing reconstruction at the time of this writing.

The operations of the Oroville Dredging, Ltd. at Oroville are gradually coming to an end, though the Company expects about five years' life for two dredges. Five dredges operated during 1912 and part of 1913, and for the 18 months ending January 31, 1913, handled 7,062,528 cu. yd. averaging 10.29c. per yd. at a profit of 5.2c. The profit for 1913 is estimated at approximately \$160,000, and from 1914 to 1918 at about \$65,000 annually, though it is questionable if both of the boats will be in operation that length of time. Exploration No. 1 sank during the year, and after investigation it was decided not to repair it. At the end of the year there will be only two dredges operating. Meanwhile the Company's holdings in Colombia are becoming productive, as mentioned elsewhere, and payment of dividends, which have been long deferred on account of financing the Colombian property, will, it is expected, be resumed early in 1914.

The other companies in Oroville have, in general, had an uneventful year. A fire destroyed a sub-station of the Pacific Gas & Electric Co., and caused a temporary shut-down of a number of dredges. Shortage of water also caused some lost time. The Vil Oro has had a good year, and has several years more to run. The Pennsylvania dredge finished its ground and is to be used to dig a small piece of ground left by the Oroville Dredging Co.'s dipper dredge. The boats that ceased operations in the Oroville field in 1913 were, Pacific 1, Boston and California No. 2, Baggett 1, Leggett dredge near Palermo, El Oro No. 1, and Exploration 1. Exploration 2 will cease operations about the last of the year, and Indiana Gold Dredging Co.'s boat will finish about January 1. The machinery from Pacific No. 1 was removed to a new hull on the American River near Auburn. The transportation and erection of the boat was completed and the new boat put in commission in less than four months, which was good work.

A New Form of Tumbler

Satisfactory trials have been made during the year with a round tumbler in place of the six-sided tumbler in general use. The new tumbler is made a little larger than actual size required for holding six buckets. This prevents buckets from striking the same point on the tumbler, and insures uniform wear both on tread faces and side or cheek faces. With a tumbler of this description the slipping of buckets is obviated, and much wear and jar is eliminated. Some dredges are using tumblers made entirely of manganese steel, except

the shaft. Other tumblers are made of carbon steel for the base, with wearing plates of manganese steel.

The re-dredging of some of the dredged areas has been advocated to some extent, but nothing has yet been attempted in this line, except as mentioned in previous reviews.

In Sacramento county the Ashburton dredge has exhausted the Company's holdings and has been shut down. The Company was negotiating, with results unknown to me at the present writing, to secure the dredge and land of the bankrupt Union dredging company having the adjoining property. The method of promotion and of financing the Union dredging company was criticized in my previous review.

An Ambitious Scheme Fails

The Tarr Mining Co., near Smartsville, after spending a large sum of money in building a complicated plant expected to handle the gravel from the old Blue Point mine, and to dispose of the tailing without objection from the Debris Commission, decided to investigate the value of the gravel that the plant was to handle; which, needless to say, should have been one of the first things, not the last done. The superintendent reported that the ground did not contain sufficient gold to warrant further development, or to finish payments on the property, so the Company retired, and the big plant which was always looked upon with amusement and suspicion by engineers familiar with the district and with gravel working, was never started. The whole business is a striking example of how an enthusiastic promoter can secure capital for an unstable enterprise, and also of the folly of going into mining without proper engineering advice. Had the services of a competent engineer been secured, much money would have been saved the shareholders.

In Calaveras county, the Mokelumme dredge, described in the *Mining and Scientific Press* of December 13, is doing good work. Construction of this dredge was commenced by the Mokelumme Dredging Co., which formerly owned the property, but owing to financial troubles, it was unable to complete the boat. The property was taken over by the Oro Water, Light & Power Co. in 1912, and the dredge, which is equipped with 7½-ft. buckets, was completed and commenced operation in February, 1913. The Isabel dredge, near Jenny Lind, has been equipped with new bucket line and a new steel bow-gantry. The Calaveras dredge in the same field has about worked out its profitable ground. The Butte dredge is said to be doing excellent work. All dredges around Jenny Lind lost considerable time in the fall from lack of water, and were obliged to shut down early in October. In Placer county the Yukon Gold Co. has built a dredge on the American river near Auburn, con-

WEAR ON BUCKET WORKING
ON A ROUND TUMBLER.

structing a new hull and using the machinery from Pacific No. 1, an Oroville boat. The Eldorado & Placer Company has a dredge at Poverty Bar, and the dredge at Loomis, belonging to the Beaver Gold Dredging Co. has undergone some changes to facilitate handling the tailing and reclaiming the land after dredging. The ground being dredged is shallow, averaging 12 to 15 ft. deep, and was formerly an orchard. Ground of this depth can be easily leveled behind the boat, which would not be possible with dredges operating on deep ground. The Yosemite Dredging & Mining Co. expects to rebuild its dredge in 1914, if some investigations now being made are successful.

During the year the dredging interests in the state were jeopardized by some proposed regulations and restrictions of gold-dredging operations, which were the object of attack in a bill introduced in the state legislature, and which found some favor among the legislators. Prompt action on the part of the dredge companies, and by the supervisors of the counties in which dredging has proved such a benefit, defeated the bill. The matter was discussed in detail in the *Mining and Scientific Press* of March 8 of last year, so it is unnecessary to go into it further at this time.

Idaho

The principal gold dredging operation in Idaho is conducted by the Boston & Idaho Gold Dredging Co. near Idaho City. The 15-cu. ft. boat of this Company made a remarkable record during 1912, handling 3,775,398 cu. yd. of material, or an average of over 314,000 cu. yd. per month. The largest yardage, 361,190, was handled during October. The ground is light and easily handled, which accounts for the high yardage, which is a world's record for any dredge. The working costs also constitute a world's record, but cannot be used in comparison with dredges in other districts. The dredge at Pierce, Clearwater county, was destroyed by fire, probably caused by a short circuit, on September 25. Insurance of \$10,000 was carried by the Company on the dredge, which was several years old. The Yuba Construction Co. has built a dredge near Salmon for interests connected with Pabst Brewing Company of Milwaukee.

Montana

The fleet of the Conrey and Poor Farm companies, working at Ruby, Montana, now consists of two boats with 7½, one with 9½, and one with 16-cu. ft. buckets. In 1913 these handled about 4,750,000 cu. yd. with a return of something over \$650,000. The big 16-ft. dredge was overhauled in July and a new screen installed. It is thought to be the strongest in use in the world, the whole screening surface being made of one-inch perforated manganese steel plates with agitating bars cast on them. It weighs nearly 100 tons. It has worked most satisfactorily. A 500-hp. motor was put in use on the bucket-chain drive and overhauling and adjusting it led to some delay. While the dredge has handled 270,000 cu. yd. in single months, even better

duty is expected. It is to be remembered that the gravel at Ruby is more thoroughly cemented than at Yuba and Oroville, and this accounts for a lower dredge duty and higher cost. Manganese steel buckets are now used on all the Ruby dredges and are giving excellent satisfaction.

Colorado

Besides the dredges operating in the Breckenridge district, a dredge and power-plant has been completed by the Tin Cup Gold Dredging Co. in Gunnison at a cost of \$180,000. Operations commenced during the last week in October, but an accident necessitated shutting down for the winter. Details are lacking as to conditions of operations, and particulars of dredge construction, which has a capacity of about 2600 cu. ft. per day. The Company owns 1900 acres of property, which is said to average 45c. per cubic yard.

Seward Peninsula

An exceptionally dry year was responsible for reducing the average yardage and output of the dredges by 30% of what it otherwise would have been had the rain conditions been normal.

The winter frost penetrated to a greater depth than usual during the preceding winter, due to the light snowfall, which afforded little protection to the ground from freezing. From June to the middle of September there was practically no rainfall, and as the summer rains and running water are the best thawing agents, a considerable part of the dredging ground, as a result, was in a semi-frozen conditions until the middle of the season. Some of the flume dredges ran successfully, and there is still, in my opinion, a future for that type of boat on the Peninsula where care and judgment have been exercised in carefully selecting the ground before building the boat. I have previously pointed out the all too frequent practice in that country of building a dredge on a property before it was known if the ground was suitable for dredging operations and if the gold content was sufficient to justify the enterprise.

Four new dredges were constructed this year. A 3½-cu. ft., close-connected bucket, flume dredge was constructed on the Kugruk river for Iver Johnson and associates by the Union Construction Co. The dredge was completed on August 23 and operated to October 10. The average daily yardage was over 2000. The labor and fuel costs were 9c. per cubic yard; the average fuel consumption being 200 gal. per day of No. 1 engine distillate. This dredge is equipped with two 50-hp. Union marine type gas-engines. A 14-in. centrifugal pump discharges 500 inches of water per minute into a steel flume 42 in. wide, 75 ft. long, with an undercurrent at the outer end 7 ft. wide and 12 ft. long. This undercurrent is lined with cocoa matting and expanded metal. About 4% of the total gold recovery was made from the undercurrent.

The Union Construction Co. dismantled the Arctic Gold Dredging Co.'s 2¾-ft. dredge on Saunders creek.

The machinery was moved to Hobson creek and installed in a new hull. Kimball and Soupe installed a 2½-cu. ft. flume dredge on Melsing creek in the Council district, which is reported to be successful. The American Dredge Building & Construction Co. built and erected a small 1½-cu. ft. flume dredge on the present beach near Nome. After running a short time, it was closed down, as it was found that the ground had been worked out by the miners at the time of the discovery was made when the present beach was rich in gold. The Anglo Alaska Gold Dredging Co. erected a 2-cu. ft. flume dredge on Sunset creek in the Teller district. This dredge was fairly successful on a creek where a hydraulic equipment, costing over \$350,000, had made a complete failure. The total cost of the dredge was less than \$40,000. The steam dredge on Osborn creek sank during the winter, and as it never had been a success, the machinery was dismantled and sold to satisfy claims for hauling. The Johnstone dredge on Windy creek in the Port Clarence mining district suspended operation in midsummer on account of frozen ground. There is supposed to be good ground ahead of the dredge, but it will be necessary to remove tundra covering the ground for a distance of 1000 ft. The owners are planning to do this in the spring. The Inmachuck Dredging Co.'s dredge closed down on October 7 after a fairly satisfactory season. The Arctic Gold Dredging Co. had considerable trouble handling large flat boulders on its ground on Hobson creek. The machinery on this boat was moved from the former dredge of the Company on Saunders creek and put in a new hull. The Ernst dredge on the beach is said to be working successfully.

The York dredge (tin) had a short season on account of lack of water, and was also obliged to cut through some of the old tailing piles to new ground. The output for 1913 has been estimated at 75 tons of concentrate. The Ruby dredge closed down on October 12. Operations during the year disclosed a greater number of large boulders in this ground than had been expected. The Solomon dredge has almost worked out the Company's holdings, and the Nome Montana dredge has exhausted its ground. The owners are now trying to dispose of the boat. The Seward dredge underwent another overhauling. The crown sheet blew down in one of the boilers and a make-shift arrangement had to be used for the rest of the season. Two old small boilers were obtained at Solomon and a small gas engine was also added. The fuel consumption is high and, while the digging end of the boat does exceptionally well, the high power cost and low efficiency of the engines add greatly to the operating cost and prevent the success that under different conditions might have followed operations. The dredge started May 20 and closed down November 20. During the first part of the season practically all of the ground was thawed with steam. The ground was from 9 to 11 ft. deep. The points were driven 9 ft. apart, and after driving were left in the ground for 12 hours.

Thawing operations were started on April 20. The boilers on the dredge were used to supply steam until the dredge started May 20; 300 ft. of ground ahead having been thawed when the dredge started operations. A 24-hp. boiler was then used, supplying steam to 24 points. The thawing costs were 12½c. per cubic yard, which included all costs of steam, hose, points, labor, and fuel. Oil delivered in a tank at Solomon cost \$1.70 per barrel of 42 gal.; freight to the dredge cost \$3.75 per barrel.

The Blue Goose dredge, operating on Ophir creek, had a successful season. This is one of the first dredges constructed on the Peninsula. It was originally a 5-cu. ft., open-connected bucket, steam-driven dredge, built at Portland, Oregon. Its present owners, in the last five years, have practically remodeled the dredge. This season they changed the bucket line from a 5-cu. ft., open-connected, to a 3-cu. ft., close-connected line, and increased their yardage 40 per cent.

The Wild Goose dredge engine was changed and some trouble and delay was experienced at first with the new one. The Shovel Creek Dredging Co. was obliged to dig considerable bedrock, as the ground is shallow. This cut down the expected yardage. Difficulty was also experienced with the engine breaking a shaft. This was successfully welded by use of thermite. Good reports come from the Flodine and Kimball dredges, which are said to be working successfully.

Altogether 1913 has not been a banner year for dredging on the Seward Peninsula, but that does not prove that other areas will not be found and, after correct prospecting, be properly equipped and successfully handled in the future. Indeed there is no doubt a chance, if suitable areas are developed, to buy some of the dredges which were improperly placed at a fraction of their first cost and move the machinery. I need only repeat what I have said in former articles, that I believe there is a field for small boats in the Seward Peninsula, but better judgment must be used, to first see that the conditions for operation and that the gold content of the ground to be handled, justify the venture.

The value of minerals exported from Broken Hill, New South Wales, during September was \$1,930,000. This included silver-lead concentrate, 30,158 tons; zinc concentrate, 35,881 tons; silver-lead ore, 2614 tons; silver-lead slime, 1384 tons; and zinc slime, 299 tons. The Central mine has opened its orebody at 1300 ft., and the North, at 1400 ft., has drilled through 112 ft. of ore. According to the *Australian Mining Standard*, recent developments show the following results:

| | Level, ft. | Lead, %. | Silver, oz. | Zinc, %. |
|----------------|------------|----------|-------------|----------|
| North | 1400 | 17.5 | 10.0 | 15.0 |
| Central | 1300 | 14.0 | 12.0 | 17.0 |
| British | 1100 | 19.6 | 13.0 | 13.3 |
| Junction | 1000 | 20.0 | ... | ... |

Statistics of exports of mineral products from Guatemala during 1912 show only 30,840 lb. of material worth \$2737.

Revision of the Mining Law

By GRAFTON MASON

Revising the mining law or leaving it intact without considering the opinions of Mining Congresses, Directors of Geological Surveys, or Secretaries of the Interior is like passing a currency bill without hearing the Comptroller of the Currency, commercial organizations, or the Secretary of the Treasury. Giving entire control of mineral legislation to those engaged in practical mining rests in the beneficiaries power to measure the extent and conditions of the Government's benefactions in disregard of the interests of the non-mining public.

If the mining law were as simple as the statement of the article, 'Revision of the Mining Law—A Protest, copied in the *Press* of October 18, 1913, the practical miner might be presumed to be content; but the author admits that he is not, and concedes that there is a general feeling that 'something is wrong.' He then brushes aside all that is supposed to be wrong by a consideration of existing statutes which are said to contain certain provisions, and these statutes are epitomized by the omission of the important terms which create the feeling that something is wrong and cause the demand for revision.

The free grant of valuable minerals in the public lands to anyone who may find them makes no provision to cover the search. Only mineral lands are open to mineral entry, and the question whether any particular parcel of public land is mineral or non-mineral is an open one until it has been judicially determined. The miner may be in possession and looking for valuable minerals with all diligence, but he is subject to contest by the Government, by claimants under any of the agricultural land laws, or by the State, or by railroad grantees of non-mineral land on the ground that the land is non-mineral. These contests involve long expensive hearings before the local land officers followed by appeals to the Commissioner of the General Land Office and then to the Secretary of the Interior. What the result will be is conjectural, for these questions appear to fall within a twilight zone of interpretation.

The question 'what is mineral land' has disturbed many tribunals, official and judicial. A proper definition was once thought to be: Land that is more valuable for mineral than for agricultural purposes; and this must appear as a present fact "from actual production of mineral, and not from any theory that it may produce it." (*Dughi v. Harkins*, 2 L.D., 721.) The generally accepted definition, however, is that given by the Supreme Court of the United States in *Davis' Administrator v. Webbald*, 139 U. S., 507-519, not "all land in which minerals may be found, but only those where the mineral is in sufficient quantity to add to their richness and to justify expenditure for its extraction." Two recent cases in the Federal

Courts illustrate one of the embarrassments of this question. In the case of *United States v. Diamond Coal & Coke Co.*, 191 Fed., 787, the Circuit Court of Appeals for the Eighth Circuit held land to be coal land, where the presence of coal in paying quantities was not shown, but geological conditions were convincing that the dip of a well known outcrop on near-by land, and traced for many miles, would carry the coal to the land in suit. Judge Bourquin in *United States v. Kostelak*, 207 Fed., 447-452, another coal case, questions the correctness of that decision, believes this is a construction and application of the law not warranted and never before arrived at by any court, nor by the Land Department of the United States; and points to the agricultural entries of lands adjoining the mines at Butte toward which their veins dip and strike, made and patented after the great value of the mines was common knowledge, with the query: "If presumption is to be indulged that a vein or lode extends under lands two miles distant from the outcropping, why not five, ten, or an indefinite number of miles; where will be the limit and how and by whom will it be determined?" It must be conceded, however, that there is greater reason for locating coal measures, by projection than the metalliferous veins at Butte.

Occupancy of Public Land

The 'Protest' asserts that present statutes grant a conditional right of exclusive occupancy of public land for the purpose of exploration for minerals. The conditional feature is said to be that the law shall be the rules, customs, and regulations of the miners of the district, who, however, cannot make a lawful rule under which exclusive occupancy for exploration may be had without a precedent discovery of the lode or vein of the rock in place which *might* contain the valuable mineral. The language of the statute is: "All valuable mineral deposits in lands belonging to the United States * * * are free and open to exploration and purchase and the lands in which they are found, to occupation and purchase * * * under regulations prescribed by law, and according to the local custom or rules of miners in the several mining districts," etc., and "the locators of all mining locations * * * on any mineral vein, lode, or ledge situated on the public domain * * * shall have exclusive right of possession and enjoyment of all the surface included within the lines of their locations."

The miner's right of possession prior to location appears to be limited to the ground actually occupied *pedis possessio*. The location is the important step; and to make a valid location there must be discovery, marking on the ground, posting, and recording. The true interpretation of these provisions does not give the

result advanced in the 'Protest' of a conditional right of exclusive occupancy of public lands for purposes of exploration, but is rather a grant of the right to continue work after finding a lead to work upon, or after discovery.

The definition of 'discovery' has not been stated uniformly with the accuracy of mathematics; but after these many years of practical application of the statute the Protestant is convinced that it means only the finding of a vein or ledge of quartz, for he asserts that there has been an erroneous supposition that the statutes required a discovery of the mineral.

The Supreme Court of the United States in *Erhardt v. Boaro*, 113 U. S., 527-536, has given an interpretation of this provision as follows: "a mere posting of a notice on a ridge of rocks cropping out of the earth or on other ground, that the poster has located thereon a mining claim, without any discovery or knowledge on his part of the existence of metal there, or in its immediate vicinity, would be justly treated as a mere speculative proceeding and would not of itself initiate any right. There must be something beyond a mere guess on the part of the miner to authorize him to make a location which will exclude others from the ground, such as the discovery of the presence of the precious minerals in it, or in such proximity to it as to justify a reasonable belief in their existence. Then protection will be afforded to the locator to make the necessary excavations and prepare the proper certificate for record."

Again in *Chrisman v. Miller*, 197 U. S., 313-323, "there must be such a discovery of mineral as gives reasonable evidence of the fact either that there is a vein or lode carrying the precious mineral, or if it be claimed as placer ground, that it is valuable for such mining."

Discovery Requirements

The 'Protest' says that the plain reason for requiring discovery of a lode, and not minerals in the lode, is that it may afford the measure to determine extralateral rights, but the Secretary of the Interior holds a different view. In paragraph 8 of the Mining Regulations, he states that the object of the provision "is evidently to prevent the appropriation of presumed mineral ground for speculative purposes, to the exclusion of *bona fide* prospectors, before sufficient work has been done to determine whether a vein or lode really exists."

The 'Protest' asserts that "there is no requirement in the statutes that there shall be a precedent discovery to make a lawful claim of occupancy of public land as placer." The Secretary of the Interior and the Courts appear to hold otherwise. See the case of *H. H. Yard et al*, 38 L. D., 59, where the Secretary cites the case of *Steele v. Tanana Mines R. Co.*, 148 Fed., 678, in which the Circuit Court of Appeals of the Ninth Circuit, said: "Although in some instances courts have questioned the necessity of an actual discovery of mineral upon gold placer ground, it is established by the de-

cided weight of authority that appropriate discovery is as necessary to the location of a placer claim as to the location of a lode claim." That case also throws some light on the nature of the 'discovery' required to support a location. The Court uses the following language: "Doubtless colors of gold may be found by panning in the dry bed of any creek in Alaska, and miners upon such encouragement, may be willing to further explore in the hope of finding gold in paying quantities. But such prospects are not sufficient to show that the land is so valuable for mineral as to take it out of the category of agricultural lands and to establish its character as mineral land when it comes to a contest between a mineral claimant and another claiming the land under other laws of the United States."

In *Waskey v. Hammer*, 223 U. S., 85-90, a placer case, the United States Supreme Court on January 22, 1912, held: "The mining laws * * * make the discovery of mineral 'within the limits of the claim' a pre-requisite to the location of a claim, whether lode or placer, the purpose being to reward the discoverer and to prevent the location of land not found to be mineral."

It is not clear what the protest means by the great mass of court decisions where the good faith of the location was not in issue being in line with the letter of the statutes in confirming rights of exclusive occupancy for purposes of exploration without there being a precedent discovery of the mineral; but it is surmised that the basis for this assertion is no more than the principle announced in *Chrisman v. Miller*: "It is true that when the controversy is between two mineral claimants the rule respecting the sufficiency of a discovery of mineral is more liberal than when it is between a mineral claimant and one seeking to make an agricultural entry, for the reason that where land is sought to be taken out of the category of agricultural lands the evidence of its mineral character should be reasonably clear, while in respect to mineral lands, in a controversy between claimants, the question is simply which is entitled to priority."

The "grant of free timber from unappropriated public land" proved a snare to one Plowman, of Idaho, who came to grief when he attempted justification of timber cutting on the public domain under the Act of June 3, 1878. His position was sustained by the Circuit Court of Appeals, but the Supreme Court of the United States held him accountable for trespass (216 U. S., 372). Plowman and the lower courts thought "the law cannot be construed to limit the cutting of timber simply to ground that is known to contain mineral" and that "the law includes as mineral lands not only those tracts in which mineral has actually been discovered and which has been or could be legally located as mining location, but also all other lands lying in reasonably close proximity to or in the general neighborhood of such known mineral tracts." The Supreme Court held that too little regard had been paid to the words of the act defining the land on which it permits timber to be cut as "mineral, and not sub-

ject to entry under existing laws of the United States, except for mineral entry." The Court holds that the right to cut is exceptional, that the only lands excluded from any but mineral entry "are lands 'valuable for minerals' or containing 'valuable mineral deposits'," and again defines 'mineral land' in the language of *Davis v. Webb*.

These few cases lead us to believe that there is something wrong with the mining law. These cases, at least, do not warrant the conclusion that all there is about the matter is that there is a free grant of minerals, with a free occupancy for the purpose of exploring for them and the free use of timber for mining purposes, and all the miner has to do is to take what has been so generously offered him, controlled only by such regulations as he may make for himself in conjunction with his fellow workers.

The order of grant is not: Free occupancy for exploration and then minerals if you find them; but is: Free minerals that have been found and then possession to recover them. This is conclusively shown by the decision of the United States Supreme Court in the case of *Belk v. Meagher*, 104 U. S., 284, wherein the court said: "The right to the possession comes only from a valid location. Consequently, if there is no location there can be no possession under it. Location does not necessarily follow from possession, but possession from location."

Ore Production of Joplin District for 1913

The carnotite shipped from the Paradox Valley region in Colorado in 1911 aggregated 1515 tons, containing 26 tons of uranium oxide; in 1912 the output was 1092 tons, containing 22 tons of uranium oxide. The decrease was due partly to inactivity of two corporate operators during part of the year, and also because many of the rich surface pockets of carnotite had been worked out. The output for 1913 will be about 1200 tons, containing about 25 tons of uranium oxide. Efforts are being made to bring about a better extraction and consequent conservation of these ores.

Iron and Steel Production in France

PARIS CORRESPONDENCE

In view of the immense progress made by Germany, the French are taking stock of their present and future in respect to iron and steel production. Although here iron and steel production cannot be said to compare in point of quantity with that of Germany or England, history attests that in point of quality France can hold her own with either. About the end of the last century, production was fairly distributed between the centre and the north of the country. The works in the east only possessed at the time a secondary importance. The discovery of the Thomas process, which made it possible to utilize the high-phosphorous ores of the Meurthe-et-Moselle, completely revolutionized the steel metallurgy of the country, and brought about the creation of France's most important metallurgical works close to the raw material. The basin of the east soon occupied a leading position, and it is there today that France produces most of her iron and steel. At the same time as the eastern basin was being developed, the centre one, handicapped by higher costs, underwent a gradual evolution, and the greater portion of its furnaces went out of blast, the district becoming a steel producer. Naturally, it retained some specialities for which it was well equipped, and in the making of which the works in the east showed no disposition to compete.

The Normand-Angevin Basin

The north, which is favorably situated with regard to coal and not too far removed from the iron ore de-

posits of the Meurthe-et-Moselle, was able to stand competition, and is equipped for using the Lorraine ores which have thus become the foundation of France's iron and steel industry. For some years, therefore, a new iron ore basin, that is the Normand-Angevin basin, has been undergoing development, and it appears destined to play an interesting part in France's metallurgical economy. This basin already supplies ore to two large works in the north: those of Isbergues and Denain, and also supplies the Trignac works. In two years the iron ore from this district will be used by the Caen blast-furnaces, and most of the metallurgical companies of the east have been exploring in this region and have solicited concessions.

The Normandy ore is considerably richer than that of Lorraine; it contains 50 to 53% of iron against 33 to 38%. But it appears that at present the iron ore beds, for area, contain less than those of the Lorraine basin. At the moment the metallurgical situation in France may be drawn as follows: In the east there are the large producers of iron, steel, and common goods. In the north are large producers, but of less tonnage, which, on the other hand, put out products of higher finish. In the centre, quantity is sacrificed for quality.

The following table indicates the position of the various companies with blast-furnaces in France on June 30, 1913 and will give a fairly complete idea of the producing capacity, in tons, per day, of the great French iron works:

| Names of houses. | Number of blast-furnaces. | | Thomas iron. | Refined cast iron. | Moulding iron. | Total production per day. |

In central France the works for producing metal for guns, armor plates, nails, automobile parts, and special steels are situated. In the southwest there are some small plants working for local clients, but seeking particularly to specialize. Finally there are on the sea coast the two works known as the Boucau and the Trignac, which are the chief source of supply for the neighboring consumers.

On June 30, there was a total of 48 works in France producing pig iron, with 159 blast-furnaces, of which 133 were in blast, with a total daily producing capacity of 15,660 tons of iron. The largest French producer today is La Société des Aciéries de la Marine, it having, however, only recently come into this premier position, which used to be disputed between the houses of Longwy and Micheville. It will be observed that the house of Creusot, once France's premier metallurgical house, now occupies a relatively humble position in the list. It has devoted itself to specialization, and has an undisputed superiority in all that refers to the metallurgy of war material. It is hinted that the house purposes struggling again for a higher position as to quantity in the list of producers, and plans to construct a model works on the eastern frontier, where it holds the concession of Droitaumont.

Output Increasing

In 1912 France produced 4,959,000 tons of iron, divided as follows: Thomas iron, 3,324,000 tons, or 67.2%; foundry pig iron, 865,000 tons, or 17.5%; refined cast iron, 536,000, or 10.9%; bessemer iron, 156,000, or 3.1%; special iron, 68,000, or 1.3%. There is scarcely any need to point out the importance of the item Thomas iron, which 30 years ago was practically only a product of the laboratory. On the other hand, refined cast iron, which in the olden times played a preponderating part when puddling was the only method known for producing iron, is annually dwindling in importance; because of the difficulty of finding good puddlers and the gradual disappearance of puddling furnaces. According to basins the production in 1912 was as follows: East, 3,455,000 tons, or 70.2%; north, 816,000 tons, or 16.4%; southwest, 260,000 tons, or 5.2%; centre, 187,000 tons, or 3.7%; southeast, 185,000 tons, or 3.3%; west, 66,000 tons, or 1.2%. The east stands easily first and does not seem in danger of having its position challenged; but it is expected that in the course of perhaps three years the order of importance of some of the other basins will be changed. For example, the west, which stands last, is expected to stand third; for the blast-furnaces of Caen will begin to produce over 300,000 tons of iron per year. And the southwest, which will have the advantage of the extension of the Trignac works, should follow close.

In 1912 the French production of iron increased by 479,000 tons compared with 1911. This is an improvement of a little over 10%. It is known that in 1913, current year, this progress has been maintained, and statistics of the first 6 months show that the average daily production has been 15,565 tons as against 14,130

tons during the first 6 months of 1912. This is a further increase of about 10%. If thus the production continues at the same rate during the second half of the year, the 1913 production may be estimated at 5,500,000 tons of cast iron in round figures. The question then arises whether France's producing activity is not about to ease off. Up to November, when this is written, the French works have been working full time, but have been living on the orders of 1912; for since the beginning of this year very few new large orders have been booked. Only large corporations such as railways, shipbuilding companies, and the war department have kept a good current business in existence; but this does not alone suffice to support the national steel industry. The country is about, then, to enter on a period when the large iron works will have to obtain fresh orders, and it is reasonably hoped that the clearer political atmosphere will permit this. It may be that the iron works will have to reduce prices in order to encourage buyers, but as far as can be judged at present the year will terminate with a good volume of business in existence. Some French authorities say that the construction of new works is being overdone, that overproduction will be the result, and a similar situation be created to that of Germany, where the iron works are said to be in a state of permanent overproduction.

Furnace Building

Coming now to the question of the future, it may be noted that in the north the Aciéries de France is going to transfer the production of hematite iron to the Calais works, and transform the two small blast-furnaces of Isbergues into larger ones for the production of Thomas iron. In this region the Forges du Nord et de l'Est is to have three blast-furnaces at the new Valenciennes works instead of the two existing. Further, in the north the Denain-Anzin concern is going to construct two new blast-furnaces at Escaudain near its present Denain works; and the end of 1914 will no doubt see the Pont-a-Vendin subsidiary of the Lens concern at work. It is designed to produce 300,000 tons of iron annually. In the east the Aciéries de la Marine is planning the construction of a new set of three blast-furnaces at the Homécourt works. These works are now considered the model works of France. The Chatillon-Commentry Co. has now completed two new installations at its Neuves-Maisons works. The Ougree-Marihay concern has re-equipped the blast-furnaces of the Chiers. The Micheville house is going to increase the capacity of its blast-furnaces by 200 tons. The Longwy concern is going to construct a blast-furnace, No. 7, of the greatest known capacity. In the southwest, the Aciéries de la Marine is repairing the two blast-furnaces of the Boucau works in order to increase their capacity, and the Basse-Loire has recently lighted its Thomas blast-furnace. In the west the Caen blast-furnaces should begin work by the end of 1915, and will produce 300,000 tons of iron per year; and finally, the special cast iron works of Paris-Outreau

is constructing a third blast-furnace; and the blast-furnace works of Rouen is preparing to produce 100,000 tons of iron per year. The total of these different projects, most of them in process of realization, means the creation of 13 blast-furnaces, not to speak of the repairing of old ones, nor of the works of Pont-a-Vendin or of Caen. These blast-furnaces will be of large capacity, and it may be calculated that the producing power of France will therefore day by day increase in three years by 1,200,000 to 1,500,000 tons; that is to say, that the annual production of the country will approach 7,000,000 tons. Hitherto the domestic demand has afforded a sufficient market for France's iron works, which have done very little as exporters. This can be seen from the following table:

| | Production of cast iron. Tons. | Home consumption. Tons. | Foreign trade. Imports. Exports. Tons. Tons. | |
|------------|--------------------------------------|-------------------------------|--|---------|
| 1903 | 2,841,000 | 2,672,000 | 27,000 | 195,000 |
| 1904 | 2,974,000 | 2,810,000 | 26,000 | 191,000 |
| 1905 | 3,077,000 | 2,882,000 | 25,000 | 220,000 |
| 1906 | 3,314,000 | 3,313,000 | 46,000 | 147,000 |
| 1907 | 3,590,000 | 3,369,000 | 36,000 | 257,000 |
| 1908 | 3,401,000 | 3,278,000 | 36,000 | 179,000 |
| 1909 | 3,574,000 | 3,451,000 | 31,000 | 154,000 |
| 1910 | 4,038,000 | 3,964,000 | 42,000 | 116,000 |
| 1911 | 4,470,000 | 4,414,000 | 57,000 | 116,000 |
| 1912 | 4,949,000 | 4,788,000 | 68,000 | 229,000 |

It is difficult to imagine that the French market will be able to absorb the increase of 1,500,000 tons in three years' time. It will be requisite, therefore, to find buyers abroad, not for cast iron, but for middle and finished products; for all the new metallurgical works under construction will have steel plant and rolling mills, and all those that are increasing their production of iron are enlarging their steel plants in proportion. The Balkan States and Morocco are expected to take up a portion of this extra production, also Central and South American countries which are indebted to France for cash, and no doubt will require again to appeal to the French money market. The danger of overproduction, which to a certain extent is already discounted by the increasing requirements of railways and naval demands, apparently does not frighten those now engaged in the iron and steel industries of France.

Oregon Metal Production

The mines of Oregon made a somewhat unexpected large increase in gold yield for 1913, compared with 1912. The mine report of 1912 showed a production of \$770,041, but the preliminary estimate for 1913, made by Charles G. Yale, of the United States Geological Survey, shows that the gold output nearly doubled in 1913, amounting to \$1,393,322, or \$623,281 more than in 1912. The mine output of silver in 1912 was 57,081 fine ounces, while the estimate for 1913 shows a yield of 218,949 oz., an increase of 161,868 ounces.

The copper output in 1912, according to mine returns, was 260,429 lb.; the estimate for 1913 is 144,796 lb., or 145,633 lb. less than in 1912. The mine report of 1912, showed a yield of 39,317 lb. of lead, but for 1913 the estimate is 96,743 pounds.

Uranium-Vanadium

Deposits of uranium and vanadium in the United States have recently been investigated by Messrs. R. B. Moore and K. L. Kithil for the Bureau of Mines. According to their preliminary report,* the carnotite deposits of Colorado and Utah are the most important uranium-bearing ores and they constitute the largest supply of radium-bearing minerals known in the world. Austria is the only other country in which large deposits of uranium-bearing ores are known; and the Austrian government considers them of such importance that it has taken entire charge of them. The deposits of carnotite in this country are much larger than those in Austria, and the output is larger also, but the deposits have been exploited and mined by rather crude and wasteful methods. Nearly all of the carnotite ore mined in the United States has been shipped to Europe for the purpose of extracting the radium contained. During the year 1912 the carnotite ores produced contained 28.8 tons of uranium oxide, which should yield 8.8 grams of radium chloride. There is only one American company that has been preparing radium salts of a high degree of radioactivity. It owns carnotite mines in Colorado and operates its own plants for the extraction and refining of radium salts.

The principal deposits of carnotite in the United States are found in western and southwestern Colorado, and in eastern Utah. The deposits in Colorado have been chiefly found along the Dolores and San Miguel rivers and their tributaries in Montrose, San Miguel, and Dolores counties, although carnotite has also been found in Rio Blanco and Routt counties. Numerous bodies of uranium and vanadium ore have been discovered in eastern Utah, principally in the Green River and Thompsons districts, but also at Split Mountain and Table Mountain. The Utah deposits contain smaller amounts of uranium and vanadium than do those in Colorado, but the properties in Utah are more accessible and have the advantage of lower transportation charges. In both cases the mineral deposits are so distant from railroads and so unfavorably situated that only the deposits of high-grade ore have been mined. In most of the localities the lack of water has made the use of the ordinary methods of milling impossible for the concentration of these ores. As a consequence, only the higher grades of ore have been exploited, the mining has resulted in much waste of medium or low-grade ore, and the shipments have been chiefly made from the small pockets of ore which contain comparatively large amounts of uranium oxide. The employment of such wasteful methods of mining and rough hand-sorting is to be deprecated, because the pockets of high-grade ore may soon be exhausted, leaving large quantities of ore containing less than 2% U_3O_8 which it might be impossible to utilize.

*U. S. Bureau of Mines, Bulletin No. 70.

The production from the Utah fields has been small on account of the low grade of the ore. During the year 1912 a total of 346 tons was shipped from Green river, Thompsons, and Cisco—the only places in Utah from which uranium ore was shipped. This ore probably averaged less than 2% U_3O_8 . The ore occurs in strata of coarse sandstone overlain with fine conglomerate. The ore-bearing portions vary in thickness from a few inches to about five feet. The carnotite occurs in cracks or fissures, in small pockets or vugs, or impregnating the sandstone. Small pockets of red vanadium ore, probably calcium vanadate, are found in some places in the sandstone. The Thompsons deposits are almost flat bedded. Mining there has been confined to the best outcrops, and the low-grade ore from hand sorting was thrown on the dump.

The principal production of carnotite ore in Colorado has come from Paradox valley and surrounding districts in Montrose and San Miguel counties. In Rio Blanco and Routt county the cost of transportation has been too high to permit of shipping ore at a profit. In the Paradox Valley region the typical ore is a sandstone so impregnated with yellow carnotite that the color is quite noticeable. A considerable part of the ore is composed of small kidneys of brown sandy clay which contain vanadium. High-grade carnotite often occurs in vugs, and this ore is so soft that it can be molded in the fingers. In places the sandstone is impregnated along the lines of stratification, and in alternate layers of carnotite and dark vanadium ore. The deposits are usually pockets of ore, many of which are large, however, as the extraction of 50 tons of shipping ore from a single claim is not unusual. The ore is found in the McElmo formation (Jura-Trias). This is a light-colored sandstone overlain in places with shale and conglomerates. Beneath it lies the La Plata sandstone, and below that the Dolores red sandstone.

Some desultory work was done in these districts from 1886 until 1909, and a considerable amount of uranium oxide was shipped from time to time. Mining in Paradox valley was not actively carried on until the formation of the General Vanadium Co. in 1909. In 1910 the Standard Chemical Co., of Pittsburgh, began work in this district, and these two companies are now the largest operators there. In 1912 the American Rare Metals Co. bought the Dolores mill in the McIntyre district. The General Vanadium Co. has about 60 claims, and the Standard Chemical Co. about 90; most of these claims are in the Long Park, Club Ranch, and East Paradox districts. The Radium Extraction Co., Crucible Steel Co., and Primos Chemical Co. have done some work on several claims in Long Park, but no large shipments have been made. The principal mine in Saucer basin is the Cliff, which has been one of the heaviest producers in the history of the industry. Much high-grade ore has been mined from pockets or vugs, but a large quantity of low-grade ore is left in the mine. In one place this deposit is 14 ft. wide. On the north side of East Para-

dox valley are the Jacobs and McKeever claims, from which 13 tons was recently shipped, which contained 3.43% U_3O_8 and 13.66% V_2O_5 . The main camp of the General Vanadium Co. is on the south side of East Paradox valley. The Company has mined nearly all of the high-grade ore, but there is a large quantity of low-grade ore in place in the mine and on the dumps. Nearby is the Joe Dandy claim, until recently a heavy producer. The American Rare Metals Co., of Denver, has large deposits of rather low-grade ore in the McIntyre district, where its plant is situated.

The price paid for uranium and vanadium ore in 1912 were approximately \$1.30 per pound of uranium oxide for 2% ore; \$1.40 for 2.5% ore; and \$1.50 for 3% ore, f.o.b. New York. For the vanadium content, 30 to 35c. was paid per pound of vanadium oxide. The high-grade ore from vugs, carrying 12 to 20% U_3O_8 , bring about \$3 per pound of oxide, f.o.b. New York. On account of the high costs of mining and transportation, it was not profitable to ship any ore containing less than 2% U_2O_8 . At present the price of carnotite ore has advanced at least 33%, and ore as low as 1% is being shipped.

Pitchblende has been found in several localities in the United States, but the only deposits which have been productive are in Gilpin county, Colorado, where five mines near Central City have shipped considerable quantities of ore.† During 1905 and 1906 the Kirk mine produced about 20 tons of pitchblende ore having an average content of 35% U_3O_8 , and over 100 tons of ore containing 3 to 4% uranium oxide. In recent years the production has been small. The German and Belcher mines during 1911 and 1912 shipped 240 lb. of ore containing more than 70%, 220 lb. containing 20%, 5 tons of 2.6% ore, and 1 ton of ore containing 2% of U_3O_8 .

The largest deposits of vanadium in the United States are near Placerville, Newmire, and Sawpit, in San Miguel county, Colorado. These deposits are in the McElmo formation. This consists of two beds of light-colored sandstone separated by a thin bed of limestone, the vanadium-bearing rock being in the lower bed of sandstone. The Primos Chemical Co. is mining extensive deposits on Bear creek, and has done a large amount of work, especially on the east side of the creek. The vanadium-bearing rock is a light to dull green fine-grained sandstone which is easily mined. The average content of the ore is only about 1.5% V_2O_5 , but it is possible to mine and treat this ore at a profit on account of the size of the deposits, the ease with which they can be mined, and the good transportation facilities. The Company has a treatment plant $2\frac{1}{2}$ miles from the mine. Other vanadium deposits of minor importance have been found in Huerfano and Eagle counties, Colorado, at Cutter, New Mexico, and in a few other localities, but no vanadium oxide has been marketed as yet.

†See Forbes Rickard, *Mining and Scientific Press*, June 7, 1913.

Mineral Production Statistics for 1913

Production of Lead

An estimate of the production of refined lead in the United States in 1913 has been compiled by C. E. Siebenthal, of the United States Geological Survey, from reports made by all lead refineries and soft-lead smelters in operation during the year. These reports cover actual production for the first ten or eleven months and an estimate for the remainder of the year, and from them the figures of production are made up **without change**. The statistics of imports, exports, and lead remaining in warehouse have been taken from the records of the Bureau of Foreign and Domestic Commerce for eleven months, the figures for December having been estimated.

The total production of refined lead, desilverized and soft, from domestic and foreign ores in 1913 was approximately 466,843 short tons, worth at the average New York price, \$41,082,184, compared with 480,894 tons, worth \$43,280,460, in 1912, and 486,979 tons in 1911. These figures do not include an estimated output of 16,338 tons of antimonial lead, against 13,552 tons in 1912 and 14,078 tons in 1911. Of the total production, desilverized lead of domestic origin, exclusive of desilverized soft lead, is estimated at 256,458 tons, against 221,480 tons in 1912; and desilverized lead of foreign origin at 54,372 tons, compared with 88,377 tons in 1912. The production of soft lead, mainly from Mississippi Valley ores, is estimated at 156,013 tons, compared with 171,037 tons in 1912.

The final figures of production of soft lead are likely to show an increase of a few thousand tons over those given here, for the reason that the argentiferous lead smelters and refineries undoubtedly treated more or less soft lead from the Mississippi Valley which is not distinguished from silver-lead ores in their preliminary estimates. It may be, with these additions, that Missouri will retain first place in the year's output of refined lead. In the mine production of lead, Missouri lost first place to Idaho. The imports of lead are estimated at 9878 short tons of lead in ore, valued at \$490,060; 46,888 tons of lead in base bullion, valued at \$2,347,148; and 41 tons of refined lead, valued at \$3655; a total of 56,717 tons, compared with 83,560 tons in 1912.

The amount of lead available for consumption during 1913 may be estimated by adding to the stock of foreign lead (domestic stocks are not known) in bonded warehouses at the beginning of the year (10,492 short tons) the imports (56,717 tons) and the domestic production (412,471 tons), making an apparent supply of 479,680 tons. From this is to be subtracted the foreign lead exported from warehouse (44,000 tons), the foreign lead exported in manufactures under drawback (7214 tons in nine months), the deduction by liquidation (391 tons), and the stock in bonded warehouses at

the close of the year (assumed to be the same as at the close of November, 6301 tons), leaving as available for consumption 421,774 tons, which by comparison with 388,148 tons in 1912, with 385,319 tons in 1911, and 379,196 tons in 1910 seems to be an excessive figure, making it seem probable that in lead, as in zinc, there has been a large increase in smelter stocks.

Production of Copper

Statistics and estimates received by the United States Geological Survey from all plants known to produce blister copper from domestic ores and from all Lake mines indicate that the copper output of the United States in 1913 will show a considerable decrease from the record production of 1912.

Decreases in production were shown by Michigan, Montana, and Alaska, and notable increases by Arizona, Utah, and New Mexico.

The figures showing smelter production from domestic ores, which have been collected by B. S. Butler, of the Geological Survey, represent the actual production of most of the companies for eleven months and an estimate of the December output. The November figures for a few companies were not available and these companies furnished estimates for the last two months of the year. According to the statistics and estimates received, the output of blister and Lake copper was 1,223,700,000 lb. in 1913, against 1,243,268,720 lb. in 1912. At an average price of about 15.3c. per pound the 1913 output has a value of about \$187,200,000, against \$205,139,338 for the 1912 output.

Figures published by the Copper Producers' Association show an output of refined copper of 1,483,480,408 lb. for the first eleven months of 1913 and indicate that the production of marketable copper by the regular refining plants from all sources, domestic and foreign, will amount to 1,618,000,000 lb. for 1913 if the December output is equal to the monthly average for the first eleven months. This compares with 1,568,104,478 lb. in 1912.

According to the Bureau of Statistics, imports of pigs, bars, and ingots for the first ten months amounted to 246,785,319 lb., and the copper content of ore, matte, and regulus imported amounted to 88,306,732 lb. If the imports for November and December were equal to the average monthly imports for the first ten months, the amount of copper entering the United States for the year was about 402,000,000 lb., against 410,240,295 lb. for 1912. Considerable of the copper imported as blister had been previously exported as ore or concentrates.

Estimates based on figures published by the Bureau of Statistics and also by the Copper Producers' Association indicate that the exports of copper for 1913 will show a marked increase over those for 1912 and

may equal 865,000,000 lb. Stocks of refined copper held in the United States January 1, 1914, are considerably less than on January 1, 1913. Foreign stocks also show a considerable decrease.

Spelter Production

The annual preliminary statement just issued by the United States Geological Survey shows that the output of spelter in 1913 established a new record, exceeding that of 1912 by a fair margin, though falling far short of the figure indicated by the phenomenal production of the first half of the year. The increase was altogether from domestic sources, as the production from foreign ores was the smallest since 1906, due, of course, to the strife in Mexico. The production during the first half of the year kept on at an increased rate over that of 1912, and somewhat exceeded the demand as shown by the increase in stocks from 4522 tons on January 1 to 21,856 tons June 30. The production slowed down materially during the last half of 1913, but the demand failed to even a greater extent, as shown by the increased spelter stocks of 36,393 tons, the greatest perhaps in the history of the industry. The extent to which production was curtailed is shown by the fact that only about three-fourths of the retort capacity available for ore was in active operation during December.

The following figures have been compiled without change by C. E. Siebenthal, of the Geological Survey, from reports furnished by all operating smelters of zinc ores, showing their output for the first eleven months of the year and their estimated production for December. Figures showing the imports and exports for eleven months were obtained from the Bureau of Foreign and Domestic Commerce, and to these figures estimates for December have been added.

The production of primary spelter from domestic ore in 1913 is estimated at 336,667 short tons and from foreign ore at 8908 tons, a total of 345,575 tons, worth, at the average St. Louis price, \$39,395,550, compared to a total of 338,806 tons in 1912, worth \$46,755,228 and made up of 323,907 tons of domestic origin and 14,899 tons of foreign origin.

The total production of spelter is equivalent to the output of 81,312 average retorts operating continuously through the year on 60% zinc concentrates. The retort capacity, available for ore, of plants active in 1913 was, at the beginning of the year, about 101,000 retorts. Many of them, of course, were used on low-grade ores, lessening their capacity. To these were added during the year 5850 retorts, making about 107,000 retorts available for ore during the latter part of the year.

Imports of zinc ore were approximately 28,541 short tons, containing about 13,036 tons of zinc, compared with 43,940 tons of ore, containing 17,567 tons of zinc, imported in 1912. Of the zinc ore imported, 18,110 tons, about 63%, came from Mexico, compared with 35,925 tons, or 80%, imported from Mexico in 1912. The ex-

ports of domestic zinc ore were 17,713 short tons, valued at \$632,000, compared with 23,349 tons in 1912. The imports of spelter are estimated at 6056 short tons, valued at about \$656,600, compared with 11,115 tons in 1912.

The apparent domestic consumption of spelter in 1913 may be computed as follows: The sum of stock on hand at smelters at the beginning of the year, 4522 tons, plus the imports, 6056 tons, and the production, 345,575 tons, gives the total available supply, 356,153 tons. From this there is to be subtracted the exports of domestic spelter, 7714 tons, the exports of foreign spelter, 5802 tons, the exports under drawback, 5751 tons, and the stock on hand at smelters at the close of the year (to be exact, on December 15), 36,395 tons, a total of 55,662 tons, leaving a balance of 300,491 tons as the apparent domestic consumption. This calculation takes no account of the stocks of spelter held by dealers or consumers. On comparing the consumption in 1913 with the previous year, it appears that the consumption has returned to the normal after the phenomenally large consumption of 1912.

Arizona's Record Production

In 1913 there was a record mine production of gold, silver, copper, lead, and zinc in Arizona, according to preliminary figures of the United States Geological Survey. The total value of the mine output was about \$71,000,000, an increase of nearly 6% over the value of 1912, which was \$67,050,784. The copper output was valued at nearly \$64,000,000; the gold at about \$3,948,000; the silver at more than \$2,263,000; the lead at \$612,000; and the zinc at \$510,000.

The mine yield of gold in Arizona in 1913 was more than 191,000 oz., an increase of 5% over the output of 1912, which was 181,996.91 fine ounces. Of this total, over 42% was taken from silicious ores and most of the remainder came from copper ores, which are undoubtedly the source of the increased gold output in 1913.

The mine production of silver increased about 8%, amounting to more than 3,773,000 oz., against 3,490,387 oz. in 1912. Most of the silver was derived from copper ore, but in 1913 the increase was due largely to shipments of lead ore and concentrates from Cochise and Mohave counties. Much silver also comes from silicious ore.

With a mine production of about 414,593,000 lb. of copper in 1913, Arizona led all other copper-producing states. The output in 1913 shows an increase of more than 49,000,000 lb., or about 12% over that of 1912, which was 365,038,649 lb. As the price of copper was slightly lower in 1913, the value of the metal increased only about \$3,500,000. There were 11 active copper smelting plants in the state, and ore and concentrate were also sent to six copper and lead plants in other states.

With an increase of more than 104%, the mine production of lead was larger than in any other year. The total output was nearly 14,000,000 lb., valued at

about \$612,000, as against 6,806,443 lb., valued at \$306,290 in 1912. The mines at Bisbee produced much lead ore, and in 1913 there was a large increase.

The mine production of recoverable spelter was about 9,100,000 lb., valued at \$510,000, which was an increase of about 340,000 lb., or nearly 4%, over the production of 1912. On account of the lower price paid for the metal, the total value decreased more than \$90,000.

California Mineral Production

California shows an increase in output of gold, silver, copper, lead, and zinc in 1913, compared with 1912, according to preliminary figures compiled by Charles G. Yale, of the United States Geological Survey. The mine figures for 1912 were \$19,713,478 in gold and 1,300,136 oz. of silver; the estimates for 1913 indicate an output of gold valued at \$20,013,374 and 1,606,261 oz. of silver, an increase for 1913 of \$299,896 in gold and 306,125 oz. of silver. There are about 1100 producing metal mines in the state, and the deep mines are yielding about 2,700,000 tons of ore annually. It is probable that the increase in gold has come mainly from the deep mines, while the added quantity of silver has come from increased output of copper and lead-silver ores.

The producing deep gold mines of the state, which yield about 56% of the total gold output each year, are between 450 and 500 in number and are situated in 26 counties. They have nearly 200 reduction plants, with a daily capacity of over 12,000 tons. The largest production from this source is derived from the five Mother Lode counties, where about 1,300,000 tons of ore is annually treated with an average recovery of \$3.70 per ton. During the year 1913 several of the old mines along the foothills and in the mountain counties have been reopened and equipped after lying idle for years, and some new 'prospects' have been opened.

In placer mining in California the dredges continue to furnish about 86% of the gold derived from the auriferous gravels. Of the total gold yield from all sources, deep and placer mines, the dredges produce about 38%. As yet there are no special signs to indicate any diminution of the total yield of gold from dredging operations, but some of the older fields are on the decline, the best ground having been worked out. A few of the companies have entirely worked out the paying ground in their holdings and have ceased operations.

Dredging has the advantage over most forms of placer mining that it requires less water in proportion to the quantity of gravel handled, and dredge miners are not materially affected by dry seasons, which occur occasionally in California. The winter of 1912-13 was very dry and there was a scarcity of water for mining operations. As a result the output of the hydraulic, drift, and surface placer mines of the State was restricted. The hydraulic mining industry suffered most and many of the mines had only a few weeks' water

supply to wash the gravel, and others only a few months' supply. The hydraulic mines now produce only about 8% of the placer gold yield in California.

Contrary to expectation, the copper output of California in 1913, according to preliminary estimates, exceeded that of 1912, when the mine production was 33,451,672 lb. The estimate for 1913 shows an output of 36,700,430 lb., an increase of 3,248,758 lb., notwithstanding continued agitation by farming communities against the damage claimed to be done by smelter fumes and the fact that several of the larger copper-smelting plants, idle from that cause in 1912, still continue unproductive.

Lead mining in the state made a marked advance in 1913. The mine report for 1912 showed a lead output of 1,144,731 lb., while the estimated returns for 1913 show a yield of 5,060,841 lb. This is an increase of 3,916,110 lb., and is due mainly to the renewal of mining and shipping operations of the Tecopa Mining Co., of Inyo county.

In zinc mining an advance in output is also shown, though it is small. In 1912 the mine report showed a yield for California of 4,345,591 lb.; the estimate for 1913 is 4,500,000 lb., an increase of 154,509 pounds.

Idaho Metal Output

In 1913 the metal mine output of Idaho was so much increased that the total value exceeded that of the record year, 1906, according to preliminary estimates of C. N. Gerry, of the United States Geological Survey. The value of the gold, silver, copper, lead, and zinc mine production was over \$23,500,000, an increase of over \$2,000,000, or nearly 10%. Record productions were made in silver, lead, and zinc; and substantial increases were made in output of all metals but gold, which remained close to the yield of 1912, the figure for 1913 being \$1,373,000. To compensate for this loss, the gold output from dredging continued to increase and that from copper ore was greater since the Lost Packer smelter was operated.

The mine yield of silver output increased 20%, from 8,294,745 oz. in 1912 to about 9,970,000 oz. in 1913, a large increase even over the previous record of 1906. In silver output the state, which in 1913 had a value of nearly \$6,000,000, was only exceeded by Nevada, Utah, and Montana. Nearly all this silver was derived from lead ore and concentrate, shipments of which were unusually large.

The copper output from Idaho mines increased from 7,492,152 lb. in 1912 to about 9,312,000 lb. in 1913, an increase of over 24 per cent.

The lead mine production increased from 284,000,000 lb. in 1912 to nearly 311,000,000 lb. in 1913, or over 9%. At the average price for 1913, this total was valued at more than \$13,500,000. Probably 93% of the lead came from the Coeur d'Alene region of Shoshone county, and the remainder from Lemhi, Fremont, Blaine, and Custer counties.

The record mine production of zinc ore and concen-

trates in Idaho in 1913 increased the spelter output from 13,905,502 lb. in 1912 to 23,594,000 lb. in 1913, an increase of nearly 70 per cent.

Two smelting plants within the state were active in 1913, one a lead plant at Clayton, now owned by the Red Bird Smelting Co., and the other a copper matting plant at Ivers. Both are in Custer county. Four dredges were operated, two at Idaho City and two in Lemhi county. The construction of a fifth one on Bohannon bar, Lemhi county, was completed.

Nevada Metal Output

Nevada's mines yielded in 1913 from ores sold or treated, \$36,374,000 in value in gold, silver, copper, lead, and zinc, according to preliminary estimates of V. C. Heikes, of the United States Geological Survey. Of this total, which is about 5% less than in 1912, the value of copper forms the largest part, or 37%; that of gold, 33%; that of silver, 25%; and the values of lead and zinc each about 2 per cent.

The mine production of gold decreased about 10%, from \$13,456,180 in 1912 to \$12,072,000 in 1913. The silicious ores cyanided were the main source of gold, which, in the form of bullion, was shipped chiefly from Goldfield, Tonopah, Fairview, Wonder, Virginia City, Manhattan, Round Mountain, National, and Seven Troughs. An increase estimated at 15% in the Nye county production of gold, from \$3,123,935 in 1912 to \$3,602,753 in 1913, is due to the large tonnage of silver ore treated at Tonopah and of gold ores at Manhattan.

Nevada in 1913 was the leading state in silver production, which came mainly from the silver ores at Tonopah. The mine production increased to about 15,300,000 oz., or about 7%. Eleven of the Tonopah mines produced 11,923,651 oz. of silver, which was extracted from the ore largely by the cyanide process. In 1912 the district yielded 10,144,987 oz. of silver. The Belmont mine, followed by the Tonopah Mining and West End Consolidated, were the largest producers. On the Comstock lode in Storey county the silver ores yielded about \$1,248,000 in gold and silver. This is slightly less than the output valued at \$1,352,089 in 1912.

An increase estimated at 2% in the mine production of copper, from 86,477,494 lb. in 1912 to about 88,368,890 lb. in 1913, is due to a slight increase in the output of the Nevada Consolidated and Giroux mines from copper 'porphyries' at Ely and in a larger output of copper matte at the Thompson smelter from Mason Valley, Nevada Douglas, and custom ores.

The lead mine output decreased from 19,500,100 lb. in 1912 to 15,300,000 lb. in 1913, or about 21%. This decrease is largely due to the decline in shipments from the Bullionville tailing dump near Pioche. The Yellow Pine district in Clark county had its usual output of about 6,500,000 lb. The lead mines in Eureka county did not all resume work, but the production of lead was greater than for several years. The output of recoverable spelter from zinc ores sold or treated

increased from 13,322,988 lb. in 1912 to 15,137,000 lb. in 1913, or about 13%. Practically all of this output is from the Yellow Pine district from carbonate ores.

Utah Metal Output

Utah mines in 1913 produced over 10,250,000 tons of ore with recoverable gold, silver, copper, lead, and zinc valued at \$43,000,000, according to the preliminary estimates of the United States Geological Survey. The tonnage shows an increase of about 32%, but the total estimated value is only slightly larger than in 1912. No new mines of consequence were put in operation, but those having large development and improvements in handling greater tonnages increased the ore output. Notable tonnages of ore were mined and shipped daily from the Utah Copper mine to its mills at Garfield where the treatment of the ore concentrated increased from 18,000 tons during the first part of the year to more than 21,000 tons per day during the latter half of 1913. The output of Bingham was the largest in the history of the camp, increasing from 6,567,948 tons in 1912 to over 9,300,000 tons of ore mined in 1913. The Tintic district mines yielded approximately 390,000 tons of ore, all of which was of shipping grade excepting a small tonnage of dump ore treated locally by the cyanide process. Ore mined at Park City aggregated about 225,000 tons.

In gold yield a decrease was noted, due largely to the closing of the Mercur gold mines. This loss was partly made up, however, by the increase in gold from copper ores, bringing the total value of the gold produced to about \$3,581,900, which is about 16% less than that of 1912. Mining of true gold ores on a large scale is on the decline in Utah.

The silver yield of Utah is principally from the lead ores, but although there was a material increase in the lead output in 1913, the silver yield from this source decreased. The mine output aggregated about 12,500,000 oz., which is about 9% less than in 1912. Park City, Bingham, and the Tintic district mines yielded nearly all the silver. Larger tonnages of lead ore with low silver content were shipped from Bingham and a notable silver decrease was indicated in the Park City district for 1913. Most of the silver is recovered at the smelters, but recently the use of the cyanide process on Bingham and Tintic ores has been encouraging.

The copper mine output, which has broken previous yearly records, reached 137,307,485 lb. in 1912 and slightly over 158,200,000 lb. in 1913, an increase of about 15%. Much of this increase was made from the 'porphyry coppers' in Utah, all of which had larger production of copper, aggregating 131,000,000 lb., increasing 22%, against 102,662,335 lb. in 1912.

The lead mine output shows an increase of nearly 12% in 1913, reaching the total of 156,679,000 lb., against 140,311,135 lb. reported in 1912. The production of zinc ore and concentrate shipments remained about the same as in 1912, yielding over 17,000,000 lb. of recoverable spelter.

The California Mother Lode and the Plymouth Mine

At the annual meeting of the London, Australian & General Exploration Co., Ltd., held in London early in December, W. J. Loring made the following remarks with reference to the Mother Lode and the Plymouth mine:

The Mother Lode of California, in which the Plymouth mine is situated, was prospected in the early days, with the result that highly profitable ore was found at or near the surface in rather widely-separated areas. In the late eighties, one mine after another closed down on account of having reached, as was thought, the end of profitable zones in the bottom of the mines, they having been highly productive down to 1200 and 1500 ft. After the mines had been lying idle for a number of years, syndicates or private companies were formed to reopen some of these mines. After sinking from 90 to 300 ft. below the old workings, profitable ore was discovered, and, as a result, other mines were reopened and good results were obtained. The mines were equipped for a second time, and another series of highly productive results were obtained. When at a depth of from 2000 to 2500 ft., another poor zone was encountered, similar to the one found at about 1000 to 1500 ft., and, without considering what had occurred at the shallower depth, the mines were shut down, exactly in the same manner as previously. After these plants had been sold, or demolished, a third series of investors took an interest in the properties, and for a third time the mines were reopened and profitable ore was again opened quite similar to that previously opened. The result is that the mines now at work on the Mother Lode are down to a depth of between 2500 and 4000 ft. on the incline.

Development at the Plymouth Mine

Highly profitable results are at present being obtained at a depth of 4300 ft. on the underlie in a mine which is situated about nine miles south of the Plymouth Consolidated. On a visit to California, 21½ years ago, I was approached by some of the principals in the Plymouth Consolidated, by whom I had been employed for 18 years, who made a proposal that I should endeavor to handle the Plymouth Consolidated group. Before recommending this property, Messrs. Bewick, Moreing & Co. considered it necessary to investigate thoroughly what had happened in other mines along this line of lode. With that object in view, the services of Malcolm MacLaren were secured, and, together with that gentleman, I investigated the points referred to. Having an intimate knowledge of other mines on the Mother Lode, and what they had done, and supported by the strong recommendations of Mr. MacLaren that we could expect to prove the downward continuation of profitable ore in the Plymouth Consolidated by deeper sinking, the California

Exploration Co. was formed. The unwatering of the mine commenced with two bailing tanks, operated by an electric hoist, and 64,000,000 gal. of water was removed. When unwatering had reached the 950-ft. level, the station was found to be in good condition. By the time the water had been lowered to 1140 ft., an inspection had been made of the southern workings off the 950-ft. level, and sampling proved the value to be \$9.16 per ton, and upon reaching the 1140-ft. level it was found that the south drift had collapsed. No attempt was made to reopen it, but a winze which extended from the 950 to the 1140-ft. level was cleaned out and on the latter level there had been stoped nearly 200 ft. The ore remaining in the back averaged \$19.34 per ton over a width of 41 in. By this time the water had been reduced to the bottom of the mine, the 1600-ft. level was cleaned up, and driving north was commenced. The orebody on this level is 160 ft. east of the shaft. The vein exposed in the drift was sampled, showing unprofitable ore, although the width was about 16 ft. Driving south was continued for a considerable distance, when profitable ore was opened, and for 115 ft. the average value was \$6.02 per ton over a width of 5 ft. It should be mentioned that this was north of the downward continuation of the original shoot worked by the former owners. An old winze was found below the 1600-ft. level, at a point 63 ft. north of the shaft, and, after cleaning it out to a depth of 75 ft., the first sample across the bottom assayed a value of \$17.18 per ton over a width of 30 in. Sinking was continued in more or less profitable ore to the 1850-ft. level, or 250 ft. below the 1600-ft. level. At the same time driving south had been commenced on both the 1500 and 1600-ft. levels. In the 1500-ft. level, 195 ft. of ore was opened, of an average value of \$4.36 per ton, over a width of 3¼ ft., and the east and west cross-cuts at 116 ft. south showed 10 ft. of ore worth \$8.56 per ton. On the 1600-ft. level the ore was 5 ft. wide for a length of 255 ft., and had an average value of \$6.96 per ton, while the cross-cuts at 87 and 153 ft. south proved a width of 19½ ft. with an average value of \$5.12 per ton, which must be considered satisfactory. At the 1850-ft. level, opened up by the winze, good ore was opened from the beginning, and 334 ft. of driving proved an average width of 4½ ft., and assay value to be \$6.32 per ton over the total length. When the end of the shoot had been reached, driving was discontinued and deeper sinking commenced, with a view to proving the downward extension of the ore. When the 2000-ft. level was reached, the vein where cut showed 21 ft. of ore which averaged \$5.78 per ton, or, taking a section, the average value for 10 ft. was \$8.80 per ton. Driving south was continued for 90 ft. The average value of the ore for a distance of 120 ft. was \$15.86 per ton over a width of 7¼ ft. There are parts standing in the south face at present worth \$288 per ton. This is, of course, from special samples, but taking it as a whole it is a magnificent body of ore.

The resources of development in this mine have not by any means been exhausted.

Apparently the second series of profitable ore-shoots has been entered, the same as has been found in other mines on the Mother Lode, whereas other mines have entered their third series, and if there is a third series in the Plymouth, of which there can be very little doubt, there is at least 2000 ft. still to go before reaching the greatest depth worked by other companies.

This mine was worked to 2450 ft. in depth, and over a million tons of ore was taken out of it, yielding \$7,200,000, about one-half of which was distributed in dividends. Working costs in this part of California are low, and, together with loss in residue, the total will be covered by \$3.12 per ton. This is mainly due to cheap power, which is generated by water within easy reach of the mines on the Mother Lode. There has been developed 110,000 tons of ore, having a gross value of \$720,000, or a net value of \$350,000, which is equal to \$3.04 per ton; but for the purpose of all calculations, the net profit is based on \$2.46 per ton. The plant is expected to treat 8000 to 9000 tons per month, and will start about September 1, 1914. The profit obtained will range between \$240,000 and \$288,000 per year over all expenses. The property should certainly prove to be a substantial producer for many years to come.

Production of Arsenic in 1913

The output of arsenic in the United States during 1913 was all in the form of white arsenic or arsenious oxide, commonly known as arsenic, and amounted to about 2375 short tons, valued at \$142,340, against 3141 tons, valued at \$190,757, in 1912, a decrease of 766 tons in quantity and \$48,417 in value, according to the preliminary figures collected by Frank L. Hess of the United States Geological Survey.

There is so little direct profit in the manufacture of white arsenic, owing largely to the long distances it must be shipped to market, that the smelting companies make it only because they must prevent its escape into the atmosphere. If the demand and prices justified a larger output the production could be greatly increased. Arsenic is used principally as an insecticide for spraying fruit trees; in the manufacture of glass, especially plate glass; and for destroying weeds.

Metal Production of Texas in 1913

The output of Texas mines for eleven months of 1913 and an estimate for December, according to preliminary figures compiled by Charles W. Henderson, of the U. S. Geological Survey, was \$100 for gold, 401,415 oz. of silver, 260,000 lb. of lead, and a nominal quantity of copper. The greater part of the output of these metals came from the Shafter district, Presidio county. Lead-silver ore was shipped from the Sierra Blanca district, El Paso county.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Government and the Individual

The Editor:

Sir—In the issue of December 6, 1913, in your editorial comment on the reversal of the Yard Decision by the Department of the Interior, you say, "As between the Government and the individual, no questions arise until application for patent is made. Prior to that date locators must rely upon state courts for protection, though there is a shadowy right of the Government involved in protection of the public domain from trespass."

Under the rulings of the Supreme Court of the United States, unless recently reversed or overruled, a mining claim is private property. It is a contingent freehold estate, held under the following conditions: (1) Before the location can be made, there must be a discovery of mineral-bearing rock, or deposit containing valuable minerals; (2) when the location is made it must be recorded as required by the regulations of the mining district in which it is situated; (3) each year thereafter until a patent is issued for it, the locator must perform labor upon the claim or make improvements thereon to the value of at least one hundred dollars. Under the provisions of section 2324 of the Revised Statutes of the United States, every organized mining district is a quasi land district, the records of which are notice to the Government and its officers as they are to all others.

There should be no question of the right of the Government, at all times to bring suit to have a mineral location set aside and canceled on the ground of fraud in its inception, or for failure on the part of the locator to comply with the terms of the grant.

I am one of those who believe that the courts are the proper tribunal for the settlement of all disputes, whether arising between the Government and a citizen, or between private individuals. The courts are the bulwark of the liberty of the citizen, and any assumption of judicial power by an administrative bureau is a menace to the freedom guaranteed under our constitutional form of government.

HENRY S. HAZLITT.

Dixie, Idaho, December 12, 1913.

Specialism and Efficiency

The Editor:

Sir—Mr. Sydney Addison's articles on the design and erection of milling plants, which have appeared in your journal of late, are of more than usual interest, and he is to be congratulated on the definite stand

taken in a subsequent letter with regard to the value of a specialist in connection with special work. As he says, a remedy for the many gross blunders connected so often with mill design and erection may be found in the employment of a metallurgical engineer, assisted by a chemist if necessary, to devise treatment; the same metallurgical engineer, assisted by a mechanical engineer if necessary, to design the plant and estimate the cost; and the same metallurgical engineer, assisted by a constructing engineer, to supervise the installation. A metallurgist has to run the plant, not a mining engineer, and it is only right that all phases of design and erection should be under the control of a metallurgical specialist.

The same views were propounded by a correspondent in a London contemporary, *The Mining Magazine*, some time back. Local opinion was, however, on the side of the general practitioner. A reply was published from one of the latter, who deplored the confined field which would be left for the mining engineer if a specialist were engaged for special work. An imaginary example was quoted of a cyanide 'specialist' having been called in to advise treatment on a copper ore, and who advocated cyanidation. The moral pointed out was that the mining engineer, "of broad training," would have seen that smelting was the correct method. Such an argument would only escape severe criticism in a centre where metallurgical decision was made by the mining engineer, and where the metallurgical specialist was only required to fill positions as working operator. In the first place, the phrase 'cyanide specialist' or 'cyanide expert' is a term which generally denotes a limited experience, coupled with a swelled head. A metallurgical specialist must be conversant with the metallurgy of a metal or group of metals. Knowledge in one detail of treatment does not permit him to assume the consulting position of a specialist.

The correspondent referred to is inclined to deery the work of specialists on account of their limited outlook which might result in taking a too narrow view. In other words, if the mining engineer who makes this statement was suffering from concussion of the brain he would prefer the services of an ordinary *medico* in preference to those of a specialist for fear that the latter might turn out to be a chiropodist who would insist on massage of the toe joints as the correct treatment.

A glance through the professional directory of *The Mining Magazine* indicates that, as far as London is concerned, there is practically no metallurgical influence to moderate or control the connection between the mining engineer and the metallurgical machinery houses. This is a situation which, for obvious reasons, neither the one nor the other desires altered. On the other hand metallurgical specialists were somewhat elated by a recognition of their status by the late President of the Institution of Mining & Metallurgy who, in his inaugural address (March 21, 1912, stated that " . . . the fact was overlooked that the metallur-

gist was a specialist, whom they, as mining engineers, gladly recognized as being no less important to the success of mining enterprise than themselves." Hopes ran high, but subsequent official utterances, aided by an influential press, have since clearly defined the profession as consisting of mining engineers—and the rest.

The final paragraph in the last letter published in *The Mining Magazine* on the subject leaves no doubt as to the position the mining engineer insists on assuming with regard to metallurgical matters. "The subsequent work of the specialist in designing and laying out the mill work that is to embody the scheme of treatment selected is of extreme importance, but it must be controlled and directed by the all-round engineer, who alone should be held responsible." The need for the specialist is admitted but he is to take a subordinate position; and his work is to be controlled and directed by a man with no special knowledge. Of what use is any specialist who is not allowed a free hand; and what more damning influence on initiative and perseverance could be conceived than by the adoption of such a method. How easy and safe and unselfish for the 'all-round' engineer to assume responsibility when he has a specialist of proved ability and professional reputation to advise him, and when he knows that the glory goes to the person assuming such responsibility.

'SPECIALIST.'

Bulawayo, Rhodesia, December 10, 1913.

Lead Salts in Cyanidation

The Editor:

Sir—In M. W. von Bernewitz' article on 'Lead Salts in Cyanidation' in the issue of November 15, he states that, "Litharge has been used by C. M. Eye to good advantage, instead of lead acetate in treating reground tailing, etc. Only 1.5 lb. of the former salt was used, against 2.5 lb. of the latter; the litharge cost half as much and showed a saving of 30 per cent."

An inspection of these figures show that the saving would be 70% instead of 30% as stated. In Mr. Eye's notes he said "reduced to 30% of original cost," which would correspond with the data given.

JOHN B. LIVINGSTON.

Chicago, December 12, 1913.

Wyoming Metal Production

The output of Wyoming mines for eleven months of 1913 and an estimate for December, according to preliminary figures compiled by Charles W. Henderson, of the United States Geological Survey, was \$26,100 for gold, 1040 oz. of silver, and 437,000 lb. of copper, compared with \$22,235 for gold, 265 oz. of silver, and 25,080 lb. of copper in 1912. The principal producing mining districts in Wyoming in 1913 were the Atlantic City (or South Pass) district, Fremont county, with output in gold bullion and cyanide precipitates; and the Hartsville district, Platte county, with output in silver-bearing copper ore.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

In New Caledonia there are 800 nickel concessions, but only 40 are being developed.

Total working force at Panama canal at the end of October numbered 36,426 people.

Minimum wage of miners at Rio Tinto, Spain, is 3 pesetas, or 58 cents, per day of 8½ hours.

Mineral production in South Australia in 1912 was \$2,880,000, an advance of \$216,000 over that of 1911.

Practically all of the carnotite ore mined during the year 1912 was shipped abroad. At this time the Colorado deposits are furnishing three times as much radium from its deposits as all the rest of the world put together.

Copper ingots for the Royal Mint, London, must not contain less than 99.8% copper, and not more than 0.005% lead, 0.005% tellurium and selenium taken together, 0.001% bismuth, 0.001% tin, 0.001% antimony, 0.01% iron, and 0.02% arsenic.

Coins valued at \$1,108,325 were made at the mints of the United States in November. These consisted of 30 double eagles, 235 half dollars, 248,235 quarter dollars, 5,450,000 dimes, 9,657,285 nickels, and 1,768,518 pennies (one cent), a total of 17,124,303 pieces. For the Philippine Islands, 360,000 ten-centavo pieces were made.

Steel plates in sluice-boxes get highly polished from the flow of water, sand, and coarse gravel through them. It is found that this is important for the life of the plates. A 0.75% carbon steel is practically as good as 1.25%, and much easier to make plates from in the rolling mills. With such plates it is possible to use a 2% grade in the boxes, as compared with 6% for rails. The life of plates is from 10,000,000 to 12,000,000 tons, against 200,000 for rails. Plates are being tried at Lagrange hydraulic mine, Trinity county, California.

Recent determinations made by G. K. Burgess and R. G. Waltenberg show the following melting points:

| | °C. | °F. | | °C. | °F. |
|-----------------|------|------|--------------|------|------|
| Titanium | 1795 | 3263 | Iron | 1530 | 2786 |
| Vanadium | 1720 | 3128 | Cobalt | 1478 | 2692 |
| Chromium | 1520 | 2768 | Nickel | 1452 | 2545 |
| Manganese | 1260 | 2300 | | | |

The determinations were made with a micro-pyrometer and the metals were melted in hydrogen gas to prevent oxidation. In some cases the metals were melted in an Arsem electric-vacuum furnace.

Sand for filtration plants should be clean, with either sharp or rounded grains, entirely free from clay, dust, or organic impurities, and if necessary should be washed to remove such materials from it. The grains should all of them be of hard material which will not disintegrate. The effective size should not be less than 0.25 nor more than 0.35 mm. The uniformity coefficient should not be more than 3. The sand should be free from dust and contain not more than 1% finer than 0.13 mm., and should be entirely free from particles over 5 mm. diameter. The sand should not contain more than 2% by weight of lime and magnesia taken together as carbonates. Gravel for the floor of filters may be broken trap rock or granite screened to the proper sizes, or gravel screened from sand and gravel banks of a sandy nature. Gravel screened from hardpan or clayey material cannot be sufficiently cleaned. The gravel should not contain more than a very small amount of shale or limestone, and should be washed entirely free from fine material.

In steam-shovel operations the method of moving the Keystone drills, used for drilling blast holes, has been greatly expedited by the use of steam cranes.

METHOD OF HANDLING CHURN-DRILLS.

Formerly the drills were moved by their own power, and roads or track were necessary in moving from one position to another. The crane method has resulted in a saving of time and money. The halftone shows the crane in use at the Nevada Consolidated property.

Special Correspondence

MEXICO

MINING CONDITIONS. — SMELTERS. — HYDRO-ELECTRIC POWER-PLANTS. — FINANCIAL SITUATION. — PETROLEUM. — COPPER COMPANIES. — CONDITIONS IN NORTHERN MEXICO. — EL ORO AND PACHUCA.

The mining industry of Mexico was affected to a greater extent in 1913 than in either of the preceding two years of political trouble. Government statistics covering the first

Rebel depredations during the year did not extend to the big power-plants supplying current to mining districts, although trouble seemed imminent on several occasions. The El Oro and Pachuca districts received continuous supplies of power from the Necaxa plant of the Mexican Light & Power Co., and the Guanajuato Power & Electric Co. and the Chapala Hydro-Electric Co. suffered no interruptions. The Mexican Northern Power Co., the Canadian concern building the Conchos river dam and power-house, and which will eventually supply power to important Chihuahua mining districts, was compelled to suspend work, due to the impossibility of securing supplies. The dam has been built to an elevation of 144 ft., and the power-house is practically completed, with much of the machinery in place. The Company reports that its properties have not been damaged.

MAP OF MEXICO.

two months of the present fiscal year (July and August), which are the latest at hand, show a decrease in exports of mineral products of \$9,871,938 compared with the corresponding months of the last fiscal year. General conditions were bad at the opening of 1913, and after the overthrow of the Madero government and the launching of the revolutionary movement against Gen. Huerta, they steadily grew worse. Rail communication between the interior of Mexico and the American border was stopped early in the year, and repeated attempts to reestablish it have been unsuccessful. Scores of bridges and station buildings have been destroyed, long stretches of track have been wrecked, and many trains have been dynamited.

The Torreon, Velardeña, and Matehuala smelters were forced to close during the first half of the year. The Aguascalientes smelter has been able to operate almost continuously, but at reduced capacity. The smelter at Chihuahua has been shut down at intervals, but has operated during the greater part of the year, and the same has been true of the smelters at Monterrey. The Towne smelter at San Luis Potosi was able to operate until August, when inability to get coke caused a shut-down of two months. The plant was again forced to suspend operations in December.

Financial disturbances have resulted from the inability of the Huerta government to secure a foreign loan, due to the attitude of the United States, and high exchange rates have prevailed since early in the year. In April a 10% export tax on all gold not sold to the Exchange Commission, at the established rate of \$1.33½ per gram, was decreed, and has been in force since that time. An executive decree issued in November doubled the stamp taxes, including those pertaining to the mining industry, and increased the tax on crude petroleum produced to 75 centavos per ton. These increases became effective December 1. Discovery that Mexican pesos were being extensively melted for exportation in the form of bars, their silver value under prevailing exchange rates being greater than their value as Mexican money, resulted in an executive decree in October providing severe punishment for those guilty of such practice. During the latter part of the year the government recoined many silver pesos into 50-centavo pieces. The increased revenues for domestic expenses resulting to producers by reason of the high rates of exchange are offset to some extent by increased costs of operation and marketing, due to disturbed conditions, and now by increased taxation.

Petroleum production continued to increase during 1913.

and in a memorial protesting against a heavy increase in taxation, prepared by producers and submitted to the government in November, the production for the year was estimated at 3,955,228 tons. At the opening of 1913 there were 64 producing wells in the Tampico territory, with a possible production of nearly 200,000 bbl. per day. The year's exports through the ports of Tampico and Tuxpam have been heavy, increased transportation facilities having been provided. In November, rebels attacked the port of Tuxpam, and in December the port of Tampico, and the petroleum industry was temporarily affected as a result. When the rebels entered the Tampico territory, the American government warned them that foreign properties must not be molested, and this warning proved effective.

Shipments from the Coahuila coalfields were stopped with the cutting of railroad communication in Coahuila, early in the year, but a number of the concerns continued operations for a time and accumulated big reserve supplies of coal, which were burned when the mines were dynamited by the rebels.

The Mazapil Copper Co., one of the important copper producers of Mexico, was forced to suspend operations in April. The Company has a copper smelter at Concepcion del Oro, Zacatecas, and a lead smelter at Saltillo. Later in the year the Saltillo smelter was blown in again, but did not operate long. In 1912 Mazapil averaged 495 tons of fine copper, 63,000 oz. silver, and 1200 oz. gold per month. In the first 10 months of 1913, Greene Cananea had a production of 36,685,000 lb. of copper, and complete returns for the year will show about 43,000,000 lb. The 1912 production of Greene-Cananea was 48,346,000 lb. At the start of the anti-Huerta movement in Sonora, the Company had difficulties, due to lack of transportation and labor troubles. Its dividends were passed as the result of curtailed operations. The Moctezuma Copper Co. had the best year in its history in 1913. In the first 10 months the production was 30,031,600 lb. of copper, as against 32,080,099 lb. in the 12 months of 1912. Complete returns for the year will show a production considerably in excess of that of last year. The Teztlutlan Copper Co., another important copper producer, was able to operate until late in the year, when rebels made an attack on Teztlutlan, in the state of Puebla, and it was necessary to suspend temporarily. The Company is resuming. During the year a 500-ton concentrator was built.

The impossibility of securing supplies and of shipping products forced many Chihuahua mines to shut down in 1913. The same was true of Durango properties. Operations in the Santa Eulalia district of Chihuahua were well maintained, considering conditions, the ores supplying the Chihuahua smelter. The Mines Company of America closed its El Rayo and Dolores plants. Suspension of traffic on the Mexico Northwestern railway stopped shipments from Cusihiuiriac district mines. The Alvarado Mining & Milling Co. continued operations in the face of great difficulties, and made shipments of bullion by wagon-train to the border. Many of the Sonora concerns have continued operations during the year, due to the fact that after the Sonora revolutionists secured control of the state there was little brigandage, and the operation of the railroad lines enabled them to secure supplies. For months mining has been practically at a standstill in the state of Sinaloa. The important El Tajo, Panuco, and Guadalupe de los Reyes properties are shut down.

Quiet has prevailed during the year in the El Oro district of the state of Mexico, and the important concerns there have operated steadily. Labor troubles threatened at the Dos Estrellas, but the difficulties were satisfactorily adjusted, and no break occurred. Dos Estrellas production has fallen off during the year, and the dividend payment has been reduced to \$3 per share per month. There has been no interference with operations in the Pachuca district of Hidalgo, except that near the end of the year a scarcity of dynamite tempo-

rarily affected some of the companies. The Real del Monte has been milling about 40,000 tons per month and has earned big profits. Good records have been made by the Santa Gertrudis, San Rafael, and La Blanca companies.

The Amparo Mining Co., of the state of Jalisco, has paid 16% on its capital of \$2,000,000 in 1913. Production has been increased during the year. The El Favor Mining Co. became a dividend payer, disbursing \$35,000 quarterly. A 250-ton reduction plant was built by the Cinco Minas Co. and will be in operation early in 1914. The Consolidated Mining Co. built a small experimental plant at its Casados mine, and has been at work on a plant to handle 100 tons per day. Work on a 50-ton cyanide plant was started by the Amajac Mines Co., but bandit activity forced a temporary suspension of work in November. The Magistral-Ameca Copper Co. resumed work at its concentrating plant, and has been shipping concentrate during a great part of the year.

Rebel activity in the state of Guanajuato did not interfere with mining and milling in the Guanajuato district, and shipments of mill products have been made regularly during the year. Rebel activity has made it impossible for the Towne interests to continue operations at Sombrerete and Fesnillo, in Zacatecas, and the Santa Rosa Mining & Milling Co., of that state, was forced to shut down in May. Operations have been at a standstill in the important Sierra Mojada lead district of Coahuila since April. The antimony smelter at Wadley, San Luis Potosi, was forced to shut down several months ago. Operations in Oaxaca districts have been greatly curtailed during the year.

LONDON

LEVANT MINE AND 'LORDS.'—FURTHER NOTES ON GEEVOR.

A few months ago I mentioned that the directors of the Levant mine, near Land's End, were in a quandary as to the future of their operations, owing to the approaching termination of their lease, and also that there was every prospect of the owners of the mineral rights, called 'the lords' in Cornwall, demanding onerous terms for a renewal. This mine is still run by a 'cost-book' company, being the sole remaining mine of any size to stand out against the principle of limited liability. It is also the only mine in Cornwall producing both tin and copper. Another fact in connection with it that is of interest is that Francis Oats, of De Beers fame, is a large shareholder, and gives the last word of advice in connection with the policy to be pursued. It was due to him that a reserve fund was accumulated, and money spent freely on development. At the present time the mine is only just paying its way, and it is doubtful whether the board will care to renew the lease. Now comes the publication of the terms under which the lords offer the new lease. They demand the expenditure of £60,000 cash capital in improving the mine, and an advance of 33% on the dues, that is, royalties. As the dues are based on the gross output and not on profits, an increase during bad times is a serious matter. The directors urge that to spend such a sum on a mine that is fairly well equipped and drained would be contrary to the best mining policy. It will be remembered that when the lease at Dolcoath was renewed 10 years ago, the demand made by A. F. Basset, the lord, for the expenditure of £25,000 on lines laid down by his own advisors was regarded as a prodigious imposition, so that £60,000 for Levant is a 'fair knock-out,' as Bombardier Wells would say. But this does not exhaust the subject by any means, for it is necessary to add that the chief lord at Levant is the Duchy of Cornwall Office. This Office manages the estate of the Duke of Cornwall, otherwise the King. In feudal days it was the King in his personal capacity; nowadays the Office is only a government department. The administration of the Crown Lands is already known to be strict and grasp-

ing to the uttermost farthing, as heartless and soulless as a limited liability company. What will happen when all land and minerals are under the control of the government is apparently foreshadowed by the action in connection with the Levant lease. The only people likely to take the property on such terms are the promoters of the rascally type; it is impossible to imagine mining men, detached from the Stock Exchange, acceding to them.

In these notes of December 20, I recorded the results of concentration with step-classification and step-grinding tried at the Geovor tin mine, which is quite close to the Levant, and that Horace G. Nichols had read a paper at the November meeting of the Institution of Mining and Metallurgy describing the results obtained, also that Oliver Wethered, the chairman of the Company, had contributed to the discussion by announcing that this modern plant had been remodeled and Dolcoath practice substituted. This week the report of the Geovor Tin Mines, Limited, for the 15 months ended September 30, 1913, has been published. The directors here give their own version. They state that, during the earlier months of the period under review, they were "caused grave anxiety owing to the great delay in restarting the mill, and the unsatisfactory results obtained from the method of treating the ore, which necessitated very material alterations. This delay had the inevitable result of disturbing the Company's finances, and as the whole of the debentures had not been subscribed, it was necessary to obtain assistance from the principal shareholders; advances were also made by the directors." It is stated in the report that after the alterations profits were made, but the information given as to the alterations is so meagre that I will not quote it.

JOPLIN, MISSOURI

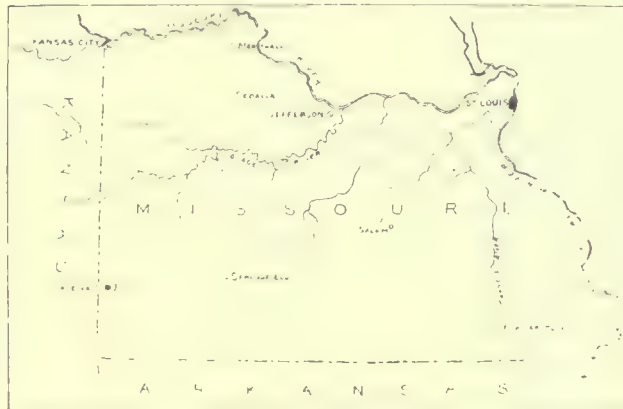

METAL PRICES.—INCREASED OUTPUT FROM OKLAHOMA.—PROSPECTING.—DEVELOPMENT AT THOMS STATION.—PRODUCTION STATISTICS.

Although prices for both zinc and lead ores throughout the year of 1913 were much lower than prevailed in 1912, when new price records were attained, production of both ores was remarkably heavy in the Missouri-Kansas-Oklahoma district. In lead ore production a new record was established, the output reaching 94,962,640 lb. and exceeding the previous record attained in 1911. The state of Kansas has always been second in the rank of the three states prior to 1913 when Oklahoma forged into second position, due to the heavy output of the Miami, Okla., mines. The Miami camp jumped from sixth to third place in the list of 21 camps, so far as aggregate valuation of the ores was concerned, while in lead ore production it went to second place, forging ahead of the Joplin camp in this item.

The year was one of importance to mining men although no high-price records were established. Probably more prospecting was done in 1913 than in any previous year in the district's history, yet there was not a great deal of development as a result of the prospecting thus undertaken. While the reports of new strikes were comparatively few, those that were made are considered of unusual worth. The greatest amount of work in virgin territory was undertaken to the north of Miami, Okla., and this field bids fair to be a heavy producer of both zinc and lead ores. As the ore deposits, as a rule, occur at great depth in that locality the cost of development is heavy. Some of the richest of soft ground development was carried on in the Thoms Station district, adjoining Joplin on the north. Not only were several large new concentrating plants constructed in that field during the year but a number of new properties are under course of development which bid fair to do their share in helping Thoms Station retain the important position it has reached because of its continuous heavy ore production of the past few years.

The blende production of the entire district amounted to

541,107,593 lb., which was valued at \$11,305,797. The calamine production for the year amounted to 40,346,251 lb., valued at \$491,245. The lead production amounted to 94,962,640 lb., valued at \$2,559,421. The total production of the district, which includes parts of Missouri, Oklahoma, and Kansas, amounted to \$14,356,461. The metal production of that part of the district which is in the state of Missouri was 451,049,423 lb. of blende valued at \$9,559,972; 40,346,251 lb. of calamine, valued at \$486,600; and 72,402,320 lb. of lead, valued at \$1,976,438, making a total of \$12,023,010. In Oklahoma the production of blende amounted to 47,043,870 lb., valued at \$877,

MAP OF MISSOURI.

997; calamine 105,620 lb., valued at \$1320; and 16,150,763 lb. of lead valued at \$418,456. The total production of that part of the district lying in Oklahoma is valued at \$1,297,775. In Kansas, the production of blende amounted to 43,014,390 lb., valued at \$867,828; calamine, 272,190 lb., valued at \$3323; and lead 6,409,557 lb., valued at \$164,527; making a total of \$1,035,678 from Kansas.

CALGARY, ALBERTA

COAL MINING IN THE PROVINCE.

The extensive railway construction in Alberta during 1913 has been accompanied by a rapid development of the coal deposits thus rendered accessible, which will form an important source of supply for railway requirements. The Brazeau Collieries, Ltd., in which the Canadian Northern railway is largely interested, is developing a large coal area near the new townsite of Nordegg, 120 miles west of Blackfalds, on the new Canadian Northern branch line from Stettler, which is now nearing completion. The first shipments are expected to be made before the end of January. Development has been in progress for 18 months by driving 1400 ft. of adits on two seams which are, respectively, 14 and 7 ft. in thickness, with a dip of only 12 degrees. The development work alone has produced 35,000 tons of coal, which is now ready for shipment. An up-to-date plant with a capacity of 2000 tons per day has been ordered, to be installed in running order by September 1, 1914, and in the meantime a temporary chute has been installed, sufficient to handle from 400 to 500 tons per day. When in full operation, the two mines now opened will employ about 450 men.

The Mountain Park Coal Co.'s mines have been reached by a branch of the Grand Trunk Pacific railway, recently completed, and now that transportation facilities are assured, will considerably extend its operations. The present output is about 500 tons per day, and by April 1914 it is expected to be increased to 2500 tons. A colony of English and Scotch miners was brought out by the Company, for whose accommodation a village of 50 houses was built at the mines. The force will before long be increased to about 800 men. The coal is high-grade bituminous, and suitable for steam purposes.

BUTTE, MONTANA

COPPER OUTPUT IN 1913.—LABOR SITUATION.—PILOT BUTTE AND BULLWHACKER.

The estimated production of copper during the past year was 290,000,000 lb. To the man about Butte it would seem that there has been no intentional curtailment of output. In fact, operating conditions have been improved at many of the mines and smelters, with a view to increasing tonnage. The figures will probably show a considerable increase in tonnage. This means, of course, that the average grade of the ore is lower. This fact is reflected at the smelters, where 5% ore is now considered first class and is charged direct to the blast-furnaces. Reviewing the statistics of production for the past 10 years, it is apparent that the copper production from Butte has remained about stationary—this in spite of the opening of several new properties. It is reasonable to conclude from these facts that Butte is at the zenith of its copper production, with a lowering grade of ore. With increasing depth, and increasing labor costs, it is not improbable that a gradual decreasing production will characterize the coming years.

At present there are more than 15,000 men employed about the mines at Butte, and the payroll is estimated to exceed \$2,000,000 per month. This local prosperity has been widely made known among the miners of the country, and in consequence the town is overrun with idle men. Men should be warned not to come to Butte this winter, as the "rustling line" at the mines is already very long and living expenses are high here. The year's payroll of the Butte mines makes large figures, estimated as follows by *The Butte Miner*:

| Company. | Amount. |
|---------------------------------|--------------|
| Anaconda | \$14,400,000 |
| East Butte | 695,000 |
| North Butte | 1,250,000 |
| Butte & Superior | 1,180,000 |
| Tuolumne | 168,000 |
| Butte-Duluth | 100,000 |
| Pilot-Butte | 60,000 |
| Davis-Daly | 292,000 |
| Butte-Alex Scott | 182,500 |
| W. A. Clark | 600,000 |
| Miscellaneous (estimated) | 500,000 |
| Total | \$19,427,500 |

These estimates cover the Butte mines alone, and do not take in the smelters, coal mines, logging camps, etc. Including all its branches, the Anaconda company's payroll alone amounts to over \$20,000,000.

It is generally conceded that labor unions run things just about to suit themselves at Butte. But once in a while they overstep the mark, and the general public rises in its wrath against some rank injustice. A case in point is now attracting local public attention. The Workingmen's Union, composed of the unskilled labor of the community, has issued an ultimatum to the effect that on and after January 1, 1914, the minimum wage for the craft shall be \$4 per day. As the skilled underground miner, under the present price of copper, receives \$3.50 per day, the humor of the situation becomes apparent to all but the employers. They have failed to see the joke, and are now banding themselves together with the intent to resist the demand. The present minimum price for unskilled surface labor is \$3.50 per day.

The Anaconda Copper Mining Co. has so far pursued the policy of letting its employees look after themselves outside of working hours, and Company boarding-houses, stores, etc., have not been introduced. Of late, however, a tendency is manifesting itself for the Company to take more interest in the welfare of its employees. This interest can in no way be construed as encroaching on the rights of the individual.

For instance, a young men's club has been started in Meaderville, and has been given material financial assistance by the Anaconda company. That, however, is to be the extent of the Company's interest in the matter. The club is to be managed by the members themselves. In similar manner it is now proposed to assist the employees of the Anaconda smelter to secure comfortable houses and a competence for themselves. This is to be done by selling them on easy terms and at low interest farm tracts of ten acres each in the Deer Lodge valley, near the works. The Company will spend large sums in improving the land, laying out the tracts, putting water and electric light systems in, and other necessities. The returns which the Company expects from the investment will be in a better, thriftier, and more contented class of employees at the smelter.

The Pilot-Butte Mining Co. is arranging to sink its shaft from the 2000 to the 2400-ft. level. A fund of \$50,000 will be necessary to do this work and to make some needed surface improvements.

The Bullwhacker Copper Co. has completed a building to house 24 precipitation-vats and the electric generator connected therewith. With this equipment it expects to be able to precipitate 4400 lb. of copper per day. Some recent developments in the mines nearby suggest that the oxidized leachable ores extend to depths of several hundred feet, which condition is encouraging to the operators of the leaching plants.

NEW YORK

UTAH CONSOLIDATED PROPERTY.—GREAT FALLS MILL AND SMELTER PROPOSALS.—BUSINESS IN COPPER IN 1913.—PRESENT COPPER SITUATION.

The Utah Consolidated is showing a surprising ability to 'come back.' Its lead output for 1913 is estimated at 17,000,000 lb., compared with 8,700,000 in 1912 and 3,000,000 in 1911. The net earnings are not expected to greatly exceed \$600,000, those of last year. The Company owns the old Highland Boy mine, which was a good producer of silver-lead ore forty years ago and gradually developed into a copper mine, with the result that the earnings of the Company in 1906 were nearly \$3,000,000. About this time, the Company, like all others in the Salt Lake district, was subjected to the attacks of 'smoke farmers' and had to curtail operations of its smelting plant. In 1910 the blow fell, for a special examination by R. H. Channing showed that instead of the million tons of 2.4% copper ore believed to be in reserve, there was actually less than 400,000 tons. There followed a period when directors, managers, and consulting engineers were busily engaged in explanations, and then the mining of lead ore was resumed. The ore reserves are now small, being given as 24,100 tons of 15% lead ore, 12,000 tons of 6.8% lead ore, and 251,500 tons of 1.9% copper ore. The Utah receives about \$40,000 per year as dividends on its shareholdings in the International Smelting & Refining Co., but, curiously enough, it was the failure of the Highland Boy mine which gave the International its greatest setback. The excellent copper-smelting plant of the International was built chiefly to handle the copper ore from the Highland Boy, and as a result has never been operated at over one-half its rated capacity.

The news that the Anaconda company will hereafter divert its concentrating ore to the mills at Anaconda, shutting down the concentrator at Great Falls, is merely a natural step in the evolution of institutions. Except to keep up capacity, there have been few good reasons for maintaining the plant at Great Falls since it was taken over by the Anaconda. There is unusually cheap water-power available in abundance at Great Falls, the plant is there and has an unusually well organized technical and laboring staff, and there is always

an advantage in having eggs in two baskets; in other words, in the event of an attempt to hold up the Company either at Anaconda or Great Falls, it would be easy to divert operations to the other place. Over against these advantages is the 280-mile haul of the ore and the fact that the coal available at Great Falls for reverberatory smelting is of every poor quality as compared with the coal available at Anaconda. The Company will unquestionably continue smelting operations at Great Falls, for the reasons mentioned, but there seems no good reason for hauling the crude ore 280 miles, only to put it through the mill and send a large portion of it to the waste heap. As a matter of fact, milling operations at Great Falls have been gradually reduced for a long time back, the mill having been used for the purpose of carrying out careful and elaborate experimental work to determine the most efficient and economical milling method. This is now being introduced in the reconstruction at Anaconda, and the Great Falls mill has therefore served a very useful purpose.

Market journals and brokers' circulars have had much to say during the year concerning the tremendous effect on the output of copper expected from the Lake Superior strike and the Mexican troubles, and it is interesting to notice that the U. S. Geological Survey estimates that the output for the year is only 1.75% less than that in 1912. Most observers would have expected that the shrinkage in the volume of business resulting from the desire of everyone to wait and see what the effect of the new tariff and banking regulations are to be, was much greater than 2% and it is doubtless the unusually heavy exports of copper that sellers have to thank for staving over a greater decline in the price of copper than the market has shown during the year. The general sentiment is that an early increase of business activity is now to be expected, and probably the price of the metal will remain fairly steady at 14 to 15 cents. This is certainly to be hoped for, as rapid ups and downs help no one but the speculator, and what the miner wants is to know where he stands and then to be able to go ahead.

BRITISH COLUMBIA

THE MINING INDUSTRY IN THE PROVINCE IN 1913.

Metalliferous mining in British Columbia during 1913 progressed satisfactorily. From the standpoint of dividends paid, the year has been the best on record, as is shown by the following table:

| | |
|--|-------------|
| Standard Silver-Lead Mining Co..... | \$ 650,000 |
| Hedley Mining Co..... | 360,000 |
| Consolidated Mining & Smelting Co..... | 464,416 |
| Granby Consolidated Mining, Smelting & Power Co. | 899,911 |
| British Columbia Copper Co..... | 88,756 |
| Le Roi No. 2, Limited..... | 43,200 |
| Total | \$2,506,283 |

The above table does not represent the total profits derived from mining operations during 1913, because profits have been earned in addition to the dividends paid by the companies mentioned, as well as by the Britannia Copper Co., the Crow's Nest Coal Co., and some of the smaller mining companies. The total production from the province during 1913, including gold, silver, lead, copper, coal, and coke is estimated at about \$2,000,000 below that of the total production for 1912, when the output was \$32,440,800; but the fact of the long period during which the strike lasted among the coal miners on Vancouver island, and which caused almost a suspension of coal-mining operations for several months, must be considered.

One of the most satisfactory features relative to the metalliferous mining industry is the fact that many of the leading companies have acquired considerable areas of mineral properties in addition to the holdings they were operating in

1912. For example, the Britannia company, operating on Howe sound, about 40 miles from Vancouver, has acquired all of the mineral-bearing zone situated between the beach and the original Britannia group of claims. These additional properties include the Goldsmith and Empress groups as well as some other claims. The Granby company has purchased some of the claims formerly included in the Van Ande company's property on Texada island, also a mine on Prince of Wales island, Alaska, formerly owned by the Hadley Copper Co., and the Midas group of claims on Solomon basin near Valdez, Alaska. The British Columbia Copper Co. has acquired a large number of claims on Copper mountain in the Similkameen district.

In the Sandon district, of the Slocan mining division, active work has been resumed on the Slocan Star, the Payne and Noble Five silver-lead mines. On Vancouver island, the Ptarmigan Mines, Ltd., an English corporation, has started opening the old Big Interior property. A syndicate of Butte mining men is preparing to work a group of copper claims near Quatsino sound. At Sooke, about 30 miles from Victoria, B. H. Johns and associates have been working on some claims containing copper-bearing ore. In the Kamloops district, the Kamloops Copper Co. has resumed operations at the Iron Mask. On Queen Charlotte islands, at Tassoo inlet, a group of claims carrying copper-bearing ore in a magnetite gangue, has been acquired by R. H. Hedley and associates of Vancouver. They have been extending the development and purpose to ship ore in the near future. In the Lillooet district, development has been resumed on the Pioneer, Why Not, and Blackbird claims on Cadwallader creek, and milling operations started on the Coronation property, after the mill had been closed down since 1910.

The most work done by prospectors has been confined principally to four fields as follows: The North Thompson river, along the line of the Canadian North Pacific railway; the Cotton-Belt, on the north fork of the Seymour river; on Eldorado and Taylor creeks, to the north from Bridge river, and situated between that river and the Chilcoten country; and on McGillivray mountain in the Lillooet district. The number of prospectors in these districts has been few as compared with the number which was formerly searching the mountain ranges for ores; but the amount of work done has been considerable. In other words, the prospectors out during the past year have been working to show up their discoveries rather than confining their energies to staking and traveling. On the North Thompson, some gold-bearing quartz has been opened during 1913, which may develop into successful mines, and as these locations are near the Canadian Pacific railway, they are of easy access. On the Cotton-Belt, some of the ores carry copper in a quartz gangue, and others carry galena and zinc in a magnetite gangue. These locations at present are handicapped by lack of transportation facilities. On Eldorado and Taylor creeks the ores are free milling mainly and contain gold. On McGillivray mountain, in the Lillooet district, about 10 miles from the line of the Pacific Great Eastern railway, where the grade crosses the mouth of McGillivray creek, considerable prospecting work has been in progress on a vein carrying silver in gray copper ore.

The only camps in British Columbia to produce any great quantity of placer gold have been at Atlin and Cariboo, where the operations have been successful and satisfactory to the owners of hydraulic claims. So far, dredging has not yet been carried on with success. Some prospecting was done on Louis creek, a tributary of the North Thompson, during the past summer, and it is claimed that about \$8000 in placer gold was recovered by individual miners. The bedrock is deep and only exposed at one point. This creek was worked as early as 1862 for placer gold. The placer gold production in the province in 1913 is estimated at \$550,000, about the same as in 1912.

erty about 20 miles from Susanville. C. E. Emerson has taken over the Wild Horse mine.

NEVADA COUNTY

Rich ore is being extracted from the lower levels of the Pennsylvania mine at Grass Valley. Forty stamps are working. During 1913 the North Star company paid \$200,000 in dividends. The Union Hill mine, at Nevada City, under bond to L. B. Doe, has been acquired by a new company, Henry Malloch being manager. The Rose Hill, near the Golden Center company's property, is to be reopened.

PLUMAS COUNTY

The Walker copper mine, 18 miles north of Portola, partly owned by J. K. Walker of Salt Lake City, has had new equipment installed. High-grade ore has been opened. Either auto-trucks or traction engines will be used to haul ore to Portola.

SIERRA COUNTY

Work has been resumed at the Columbia drift mine, 10 miles east of Forest City. Shortage of water last summer caused the shut-down. It is probable that the Omega gravel mine, on Oregon creek below Forest City, will be opened in the spring. F. O. Dale, of Oakland, represents the controlling interests. At the Sixteen-to-One mine, at Alleghany, drifts are being opened in quartz at 100, 150, and 200 ft. The mine is dry, being drained by the lower workings of the Tightner. Sinking is under way at the Plumbago mine.

On January 6 the Tightner company, operating at Alleghany, paid a dividend of \$500 per share to its 100 stockholders.

SISKIYOU COUNTY

The Highland mine, near Sawyers Bar, will be reopened on a larger scale than formerly next spring. The Forks of Salmon gravel property, operated by the Lagrange company, is to be equipped with hydraulic giants and elevators. M. A. Singer is in charge. The Forks of Salmon placer property is being sold to Los Angeles people. An elevator has been installed at the Michigan Salmon mine. Hydraulic mining is being done on about a dozen properties, there being plenty of water.

SUTTER COUNTY

The county of Sutter has commenced suit against W. J. Chaney and others to enjoin them from further dumping of debris from gold dredges into the Feather river near Oroville. The complaint is on secret file.

TRINITY COUNTY

Steel plates are being tried in sluice-boxes at Lagrange gravel mine. The Company's siphon on Stuart's fork blew up on December 20. This is a 36-in. diameter steel pipe and carries water across a cañon. A new pipe was to have been inserted. A wagon with 22 horses and 11 men have been trying to transport a new steel plate to the break, but without success. It is now to be taken there over the Buckeye ditch. The Company's officials figure that it will cost \$2000 to deliver the plate, but it must get there for the season's work.

YUBA COUNTY

Reports received at Marysville from Smartsville state that the Guggenheim drilling plant on the Yuba river was destroyed by a flood, and two valuable drills were lost.

COLORADO

CHAFFEE COUNTY

This county produced \$290,000 in gold, 154,000 oz. of silver, 2,763,000 lb. of lead, and 300,000 lb. of copper, and a considerable quantity of zinc in 1913, a heavy increase for all the metals.

CONEJOS COUNTY

(Special Correspondence.)—There have not been any very

favorable developments in the Platoro district, and no shipments have been made. There are said to be about 50 men wintering in the district. There are unconfirmed rumors regarding a discovery of copper ore near the Worrell ranch. Platoro, January 1.

CLEAR CREEK COUNTY

(Special Correspondence.)—A rich mineral discovery has been made at the Georgetown adit, on Columbian mountain. At a distance of 800 ft. from the portal, a vein has been opened, and two streaks give assays of 700 oz. of silver per ton. J. J. Keating is manager. The motor for the Capital adit has arrived, and the trolley system has been brought into use. The Onondago Mining Co. will at once enlarge the working force, and the Capital company will also enlarge operations. Good results are coming from work at the Esmeralda, Montgomery-Ward, Santiago, Little Giant, and lessees at the Jo Reynolds and Free America properties. The New Era mine at Freeland has been sold to Eastern people for \$250,000. Mineral output from the Idaho Springs district in 1913 was about \$960,000. Snowstorms have interfered with work lately.

Idaho Springs, January 1.

Clear Creek county's output of metals in 1913 was \$495,000 in gold, 424,700 oz. of silver, 4,230,000 lb. of lead, 524,000 lb. of copper, and approximately 1,500,000 lb. of zinc, an increase for all the metals except zinc. On December 24 the Edison rolls were started at the Burleigh mill.

EAGLE COUNTY

The output of this county, from Red Cliff and from Eagle (a new producing silver district in 1913), was \$42,000 in gold, 300,000 oz. silver, 1,000,000 lb. lead, and 5,500,000 lb. zinc.

GILPIN COUNTY

This county's output in 1913 decreased about \$200,000 in gold and 50,000 oz. of silver, allowing for bullion produced in Clear Creek county mined through the Newhouse tunnel.

Ore shipments from Black Hawk during 1913 totaled 76,075 tons, a decrease of 8275 tons compared with the previous year. This was principally due to the stoppage of work at the Frontenac-Aduddell and Topeka properties.

GUNNISON COUNTY

Owing to the closing of the Gold Links mine at Ohio, the county's output of bullion, ore, and concentrate showed a heavy decrease for gold. Lead and zinc production also decreased, but there was an appreciable increase in silver output, owing to the opening of mines at Whitepine and on Italian mountain.

HINSDALE COUNTY

The output from this county in 1913 showed a decrease of 400,000 lb. of lead.

LAKE COUNTY (LEADVILLE)

Including the Lackawanna Gulch district, this county in 1913 produced \$981,416 in gold, 3,200,000 oz. of silver, 2,000,000 lb. of copper, 28,000,000 lb. of lead, and 98,000,000 lb. of zinc, with a total value of \$10,000,000, as against \$11,780,131 in 1912, according to the U. S. Geological Survey. The output of zinc carbonate was 137,000 tons of approximately 27% zinc, against 142,782 tons of 29.2% zinc in 1912. The production of zinc sulphide shipped varied little from the 104,148 tons of 24% zinc in 1912. The zinc carbonate ore was treated at smelters in Kansas, Oklahoma, and Wisconsin, and the zinc sulphide was treated at the Empire Zinc Co.'s magnetic separation plant at Cañon City, at the Western Chemical Co.'s wet-concentration and magnetic separation plant at Denver, at the United States Zinc Co.'s magnetic plant and smelter at Pueblo, and at the zinc oxide plant at Coffeyville, Kansas. A total of 453,560 tons of ore was mined in the Leadville district.

MINERAL COUNTY

(Special Correspondence.)—The Del Monte mine is producing over 1000 tons per month now, in spite of the fact that it was supposed to have been worked out six years ago. The Amethyst is also producing about 1000 to 1200 tons per month, and the Bachelor and Commodore are shipping regularly. The Creede Mines Co. has been doing almost nothing but development work during the past year. Its properties are on the north end of the Amethyst, the Antlers-Park Regent, and the Happy Thought. Considerable milling ore has been developed. In the near future the Company will start the Humphreys mill, which has been shut down for eight or ten months. Shrive Collins, of Creede, is working the fluorspar deposit at Wagon Wheel Gap, and is shipping about three cars per week to the steel works at Pueblo. It is said that this is excellent fluorspar, containing over 90% pure in carload lots. On the whole, Creede is in a promising condition at present; better than for some time past.

Creede produced \$52,000 in gold, 790,000 oz. silver, 3,560,000 lb. lead, 35,000 lb. copper, and 510,000 lb. zinc in 1913, which is an appreciable decrease for gold and lead, but an increase for silver, copper, and zinc.

Creede, January 1.

PARK COUNTY

In 1913 the output of silver, lead, and copper increased, more than balancing an appreciable decrease in gold.

PITKIN COUNTY

The mineral output of Aspen in 1913 was 591,000 oz. silver and 16,780,000 lb. lead, an increase of 62,000 oz. and 8,370,000 lb., respectively.

ROUTT COUNTY

The Routt County Taxpayers' League, on January 3, reported seven union men and gave notice to every coal miner that he must get work or leave the county.

SUMMIT COUNTY

The output of gold from dredges and small mines at Breckenridge, in 1913, according to the U. S. Geological Survey, increased \$50,000, and gold in smelting ore from Kokomo, Breckenridge, and Montezuma showed an increase for the county of \$14,000. Silver, lead, and copper yields showed increases. The yield of zinc decreased, owing to the closing of the wet mill of the Wellington company during the latter part of the year, although the magnetic plant continued to be operated.

TELLER COUNTY (CRIPPLE CREEK)

During December the Cripple Creek district was visited by storms, and the output decreased. The following shows the estimated yield for the month:

| Plants. | Tons. | Av. val. | Gross val. |
|---------------------------------|--------|----------|-------------|
| Smelters, Denver and Pueblo... | 3,500 | \$65.00 | \$ 227,500 |
| Golden Cycle, Colorado Springs. | 25,000 | 20.00 | 500,000 |
| Portland, Colorado Springs..... | 8,500 | 22.00 | 170,000 |
| Portland, Cripple Creek | 15,000 | 3.00 | 45,000 |
| Stratton's Independence | 10,000 | 3.00 | 30,000 |
| Colburn-Ajax | 4,000 | 4.00 | 16,000 |
| Wild Horse | 1,100 | 4.00 | 4,400 |
| Kavanagh-Jo Dandy | 1,600 | 2.15 | 3,440 |
| Gaylord-Dante | 1,000 | 3.00 | 3,000 |
| Rex | 500 | 3.00 | 1,500 |
| Isabella | 450 | 3.00 | 1,360 |
| Total | 70,650 | | \$1,002,190 |

Dividends amounting to \$180,000 were paid in December. On January 1 the Golden Cycle company paid dividend No. 82, equal to \$45,000.

The Progressive Leasing & Development Co., operating the Chicken Hawk mine on Guyot hill, owned by the Katinka Gold Mining Co., has finished sinking, and timbermen are

now at work in the station cut out at a depth of 1250 ft. from the surface. The collar of the Chicken Hawk shaft is at an elevation of 9800 ft. above sea-level. At a depth of 500 ft., on the 350-ft. level of the Eclipse shaft, the El Oro company has opened rich ore containing tellurides. Warner and party, lessees at the Ajax company's block 13, have finished their lease. It is figured that they have netted \$125,000. According to the U. S. Geological Survey, the district's gold output showed an increase of \$176,000 during 1913.

MONTANA

FERGUS COUNTY

The Barnes-King Development Co. has acquired full title to the North Moccasin property, the final payment of \$4178.40 having been made on December 24. The full price was \$150,000, and \$5000 was paid in cash when the contract for purchase was made in August 1912. The balance, \$145,000, has come out of the mine, and in the meantime important additions to the equipment and development have been made. In November the gold output was \$27,942, and for December it is estimated at \$30,000. On account of the Heinze injunction in New York, there is \$90,000 in funds tied up temporarily.

MADISON COUNTY

It is stated that representatives of a dredging company are examining ground in the vicinity of Twin Bridges.

POWELL COUNTY

There is said to be a fair amount of active work going on in the Snowshoe district, northeast of Powell.

SILVERBOW COUNTY

The new development on the Edith May vein, at 2600 ft. in the North Butte mine, is regarded as important. Ten feet of ore containing 5.5% copper has been opened on the foot-wall. Generally the mine is looking well. An official announcement has been made by the Anaconda Copper Mining Co. that after February 1 no more ores will be sent to the Boston & Montana mill; milling will be done at the Washoe concentrating plant. Only high-grade ore and concentrate will be sent to the Great Falls smelter. The mill at Great Falls has a daily capacity of 2700 tons in its six units, and the smelter about 5000 tons per day. It is 172 miles from Butte to Great Falls, and freight on ore costs 75c. per ton. These changes will result in great economy for the Company.

NEVADA

ESMERALDA COUNTY

The Goldfield Consolidated Mines Co. reports as follows for november, 1913:

| | |
|-------------------------------|-----------|
| Ore treated, tons | 28,947 |
| Net profit | \$170,779 |
| Costs | |
| per ton. | |
| Stoping and development | \$3.26 |
| Shipping expense | 0.19 |
| Dump moving | 0.04 |
| Transportation | 0.09 |
| Milling | 1.78 |
| Marketing | 0.05 |
| General expense | 0.36 |
| Bullion tax | 0.15 |
| Construction | 0.01 |
| Flood damage | 0.01 |

Total costs\$5.94
Miscellaneous earnings 0.06

Net costs\$5.88

At a cost of \$4.48 per foot 2675 ft. of development was done.

CHURCHILL COUNTY

During November the Nevada Hills Company treated 4219 tons of ore yielding \$38,271 or \$9.09 per ton. The net profit was \$8069. Cash on hand and in banks is \$98,556, which, with supplies, concentrate, bullion, etc., makes total resources of \$181,416. A number of inquiries have been received regarding the monthly charge of \$5000, for depreciation, shown in the full reports to newspapers. This is merely a matter of bookkeeping, being depreciation allowed in computing returns subject to tax and does not effect the actual monthly earnings, hence is not included in these monthly condensed reports. The cash on hand and in banks has not increased proportionately with the monthly earnings the last two months because of some large purchases of store supplies.

EUREKA COUNTY

The new Buckhorn mill started work on December 30, and

OLIVER FILTERS AT THE BUCKHORN MILL.

is running well. It is hoped to keep mining and milling costs down to \$2.50 per ton.

HUMBOLDT COUNTY

The Mexican Gold & Silver Mining Co., operating on the Comstock lode, has decided to invest \$145,000 at Rochester. The Rochester Mining and Rochester Weaver companies' mines will be acquired, and a large mill is to be erected, these companies supplying 100 tons per day at an agreed charge for treatment. Work has been started at the property of the Highland National Mining Co., in the Tobin district, 37 miles from Battle Mountain. In one claim a shaft has opened ore assaying 29 oz. silver and 17% lead.

LINCOLN COUNTY

Instead of timbering stoped ground in the Prince Consolidated, a caving system has been introduced, costing a total of \$1.20 per ton, including ore transport. A new schedule of railroad rates has just gone into effect.

MINERAL COUNTY

The first clean-up from the Black Eagle Gold Mining Co.'s new 20-stamp mill at Rawhide has been made. The plant has a daily capacity of 100 tons. The mine has been opened to 300 ft., and reserves total 30,000 tons of \$15 ore. Twenty-five men are employed. Work at the Aurora mill continues in spite of bad weather. The 6000-ft. adit has opened better ore than expected. The marble deposits west of Mina are being reworked. According to a report from Reno, the Irondyke property, near Mina, is opening well. A mill of ten 1250-lb. stamps and cyanide plant has been erected at the Irondyke-Bley mine by the Trent Engineering Works of Reno. A large tonnage of \$20 ore has been mined. The Oneota dis-

trict is showing a fair amount of activity of late. It is 5½ miles from Sunland on the railroad.

NYE COUNTY

(Special Correspondence.)—Ten stamps are being added to the War Eagle mill. The gold and silver production of the Manhattan district in 1913 is figured at \$560,000 according to the Chamber of Mines. Of this amount the mines produced \$442,262, from 54,260 tons, an average of \$8.15 per ton. The placer workings yielded \$117,738 from 29,435 yards of gravel sluiced, an average value of \$4 per yard. The tonnage treated, and gross value of the ore milled during the year by the various mills of the camp, as nearly as can be obtained is as follows:

| Mill. | Tons. | Gross value. |
|-------------------------------------|--------|--------------|
| Associated | 3,082 | \$ 52,209 |
| Manhattan | 13,647 | 130,386 |
| Big Four | 18,294 | 79,668 |
| East Side | 103 | 1,770 |
| War Eagle (estimated) | 18,442 | 140,000 |
| Shipped by White Caps company | 692 | 38,229 |
| Total | 54,260 | \$442,262 |
| Manhattan, January 3. | | |

STOREY COUNTY

The water in the Con. Virginia winze is 120 ft. below the 2500-ft. level.

WHITE PINE COUNTY

At the Steptoe Valley Smelting & Mining Co.'s plant, Ely, Nevada, 22 Dorr thickeners are in operation, dewatering the slime, several of these machines being 50 ft. in diameter.

NEW MEXICO

GRANT COUNTY

During 1913 the copper output of the state was about 53,671,000 lb., against 29,377,966 lb. in 1912. The most of this came from the Chino Copper Co.'s mine and mill at Santa Rita and Hurley, respectively. It is stated in New York that the Chino mill will be increased in capacity from 5000 to 10,000 tons of ore per day. Water supply has hitherto been an obstacle, but that from the Lampbright creek is expected to serve all requirements. The Lordsburg and Burro Mountain districts shipped a good deal of ore.

SOCORRO COUNTY

This county showed an increase of \$100,000 in gold and 270,000 oz. of silver during the past year over 1912. Zinc production from the Magdalena district, which is the most important in the state, increased. The total yield from all districts was 32,189 tons of 39.9% zinc ore and concentrate.

SOUTH DAKOTA

LAWRENCE COUNTY

Operations at the Wasp mine were resumed on December 28 after several weeks of idleness, the result of a temporary shortage of the water supply. The water problem was solved by sinking a well deeper. The Homestake Mining Co. will install a new hoist at Lead during the current year, and also an electric distributing plant for the Company's buildings in the town.

UTAH

BOXELDER COUNTY

Near Brigham City the British-American Petroleum Co. is drilling for oil and gas. Two rigs are in use, a Standard and a Keystone. One well is now down 1300 ft., and will be drilled to 3000 feet. Sufficient gas has been tapped to supply the town. M. C. Hagan is in charge.

JUAB COUNTY

About 200 tons of 8% copper ore is being shipped from the 600 and 700-ft. levels of the Iron Blossom at Tintic. Iron ore

is not being mined at the Dragon as the United States company's smelter has plenty on hand. Lead-silver ore will be shipped as usual.

SALT LAKE COUNTY

After examining the Utah Apex mine, the sheriffs found no trace of the Mexican outlaw Lopez, who was supposed to have been killed by fume sent into the workings. In November the Ohio Copper Co.'s mill at Lark treated 66,424 tons of ore averaging 1.105% copper. Recoveries have improved lately. Costs were, mining, 28.78c.; transport, 16.04c.; and milling, 51.52c., a total of 96.32c. per ton. The month's profit was \$20,000.

SUMMIT COUNTY

On December 28 the mill, hoisting plant, assay office, and other equipment at the Daly-West mine, Park City, was destroyed by fire. This started in the boiler room, but could not be checked. The loss is \$200,000, insurance covering \$120,000. A new plant will be erected in the spring. The Thompson-Quincy mine, which is worked through the Daly-West, will be shut down for the present. Over 200 men will be out of employment.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—Involuntary bankruptcy petitions have been filed by the Washington Northern Telephone & Telegraph Co. against the Republic Mines Corporation, which owes the former \$3502. The mining company owes a total of \$80,000, of which \$50,000 is unsecured. A receiver has charge of the property. The 200-ft. level of the Ben Hur mine is opening well, and 5 ft. of \$17 gold ore was recently developed. Other levels are showing good ore.

Republic, January 2.

PIERCE COUNTY

Working hours at the Tacoma smelter were increased from 9 to 10 hours on December 30, at the old rate of \$2.25. About 250 men went out on strike, but the officials state that their places are being filled.

STEVENS COUNTY

Results of small trials in smelting ore at the Copper King, at Chewelah, have been satisfactory, and the Company is considering the erection of a smelter costing between \$35,000 and \$50,000. Further tests will be made, when coke will be used instead of charcoal. A concentrating plant may also be erected. Development has been started at the Security and Amazon claims in this district.

CANADA

BRITISH COLUMBIA

Camp Hedley had an active year, according to the *Hedley Gazette*. This was mainly due to the Nickel Plate mine. The Dickson incline shaft, which is to serve as the main outlet for ores from the property, was sunk 700 ft. It is 8 by 16 ft. in the clear, and is provided with double tracks and a manway. Diamond-drilling covered 1300 ft. during 1913. The mill treated about 70,700 tons of ore, averaging \$12 per ton in gold, with 94% recovery. The total gold output to date is \$5,413,700. A considerable amount of construction was accomplished. Development was continued at the Clifton and Oregon mines.

ONTARIO

The last quarterly report of the Beaver Consolidated states that development covered 1526 ft. and stoping 1164 sq. yd. There is 30,000 tons of broken ore in the stopes. Work has been temporarily stopped on the 700 and 800-ft. levels, and one drill is operating at 600 ft. This is on account of the limited capacity of the hoist. A new engine, capable of lifting 8000 lb. from a depth of 2000 ft. at a speed of 1200 to 1800 ft. per minute, will be running by February 1. The 600-ft. level has opened well. At 460 ft. depth, the

shoot is 600 ft. long. The 6-ft. Hardinge mill installed in the plant has increased the tonnage treated. The available balance is \$134,335. During the year ended October 31, 1913, the Coniagas company produced 3,572,399 oz. of silver from 611 tons of high grade and 54,890 tons of low-grade ore. Permission has been granted to the Cobalt Lake Mining Co. to drain Cobalt lake. Work will be started at an early date. In November the Buffalo mill yielded 100,454 oz. silver from 6174 tons of ore. The sum of \$30,000 has been appropriated for developing the Buffalo property, outside of that already opened. The mill tailing is being resampled. T. R. Jones is superintendent.

At Porcupine, the McIntyre mill, in November, treated 3965 tons of ore yielding \$30,278 in gold, with 94.3% extraction. Costs were: development, \$1.72; mining, \$2.17; milling, \$1.69; and general, \$0.66; a total of \$6.24 per ton. A new tube and Hardinge mill are being installed. On the 200-ft. level of the Tough-Oakes mine, at Kirkland lake, a shoot 18 in wide containing 65.68 oz. of gold per ton has been cut.

YUKON

The Canadian Klondyke Co.'s three dredges produced 1538 oz. gold during the last week in November. After many years of prospecting, the conglomerates opposite Quartz creek, along the Indian river, are to be opened. About 95 claims have been optioned to an American company, which will start core-drills as soon as navigation is open this spring. T. A. Fifth, of Dawson, has been acting for the owners of the claims. Telephone connection is now obtainable with Dawson from the Quartz creek district. Temperatures at Dawson on December 5 were: maximum, 5° F. below; minimum, 15° F. below zero.

KOREA

The Seoul Mining Co., operating the Suan Concession, in Whang Hai province, Korea, reports the following results for November 1913:

| | |
|--------------------------|----------|
| Stamps working | 40 |
| Time, days | 26½ |
| Ore crushed, tons | 6,337 |
| Total recovery | \$60,758 |
| Operating expenses | 25,000 |
| Net earnings | 35,758 |

The Oriental Consolidated Mining Co.'s mills treated 25,602 tons of ore in November, yielding \$140,059. The weather was dry and cold, and the Tabowie mill was short of water for a while. Retimbering the Tabowie mine shaft was completed.

MEXICO

JALISCO

Two hundred and fifty tons of concentrate was recently shipped by the Amparo Mining Co., in the Etzatlan district, to the Selby smelter, San Francisco. The product formerly went to the Torreon smelter. The annual report of El Favor Mining Co., the Makeever property in the Hostotipaquillo district, gives the following:

| | |
|-------------------------------------|-----------|
| Ore shipped to smelters, tons | 3,896 |
| Value | \$485,465 |
| Ore milled, tons | 9,213 |
| Yield | \$140,818 |
| Sales by Company's store | 112,500 |
| Profit from store | 17,827 |
| Profit from all operations | 359,100 |
| Dividends in 1913 | \$140,000 |

Ore containing 700 gm. of silver and some gold amounts to 6½ years' supply at 100 tons per day, with a large tonnage of low-grade ore. Concentrates are being sent to the Aguascalientes smelters. During the year the Southern Pacific railroad built 9 kilometres of line for the transport of ore and supplies to and from the mines.

Schools and Societies

The GEOLOGICAL SOCIETY OF AMERICA held its twenty-sixths annual meeting at Princeton, New Jersey, on December 30. The president gave an address entitled 'Some Pioneers in Gulf Coastal Plain Geology and their Contributions to Geological Literature.' This was delivered in the house of the Nassau Club. A smoker, offered by Princeton University and resident fellows of the society, was held after the lecture.

The MINING AND METALLURGICAL SOCIETY OF AMERICA is holding its annual meeting in New York on January 13. In order to transact business there must be 80 members present in person or by proxy. An informal dinner is to be held at the Engineers' Club. At this meeting the gold medal of the Society will be awarded to Mr. and Mrs. H. C. Hoover. Arrangements for the formal presentation at some subsequent date will be duly announced. The El Paso, Texas, School of Mines project is assured of success and will be opened during next fall.

The last meeting of the New York section of the AMERICAN ELECTROCHEMICAL SOCIETY was a joint one with the American Institute of Electrical Engineers and the New York section of the American Society of Mechanical Engineers, on January 10, in the auditorium of the Engineering Societies building, New York City. C. O. Mailloux presided. After the meeting members were the guests of the A. I. E. E. at a smoker held in the rooms of the Institute. The subject for the evening was 'The Power Problem in the Electrolytic Deposition of Metals,' and the program was as follows: 'The Limitations of the Problem,' by Lawrence Addicks, of the United States Metals Refining Co. This was a brief statement of the conditions imposed by practice in the electrolytic refining of copper as a typical process. 'The Mechanical Side of the Problem,' by H. E. Longwell, of the Westinghouse Machine Co. This was on the application of gas and steam for driving generators of the type required. 'The Electrical Side of the Problem,' by F. D. Newbury, of the Westinghouse Electric & Manufacturing Co.; a discussion of the application of various direct current and alternating current-direct current apparatus to furnish current of the required dimensions.

The UNIVERSITY OF CALIFORNIA register for 1912-13, contains the following announcements for 1913-14: In the chemistry courses there are 12 professors and 14 assistants. The laboratory is well equipped for research work, and is open to properly qualified graduate students, not only throughout the college year, but also during the summer vacation. For every laboratory course in chemistry, the charge will be \$5 each half-year per credit unit of laboratory work. A student, taking only upper division courses, will not be charged for more than four units, that is, the maximum fee in such cases, exclusive of deposits covering breakages, will be \$20. There are 13 on the staff of civil engineering courses. Engineering students who wish to study irrigation, can do so in connection with the College of Civil Engineering. For mechanical and electrical engineering classes there are 11 teachers. In this department, laboratory fees are at the rate of \$5 per half-year for each laboratory or mechanical practice exercise a week. The courses cover everything connected with these subjects. Mining and metallurgy classes cover mine surveying, mining, excavation, the mining laboratory, summer class in practical work, structural metal and fuels, ore crushing, sampling, assaying, metallurgy of gold, silver, quicksilver, lead, copper, and mill work. Graduate courses cover 17 units of work per week during the first half-year, and 15 units in the second half-year; including lecture and laboratory work on ore dressing, treatment, iron and steel metallurgy, mine machinery, mill design, and mining law. In all the colleges there are 7695 students of all grades.

Personal

C. E. BUNKER is in San Francisco.

EDMUND JUESSEN has gone to Colorado.

A. C. BOYLE was in New York last week.

H. FOSTER BAIN is at Jackson, California.

E. B. BRADEN has left for New York and the East.

A. E. DRUCKER is on his way from Korea to London.

W. TOVOTE has completed his work at Globe and returned to Bisbee.

JOHN H. EGGERS was down from East Rochester, Nevada, for the holidays.

E. A. LORING has been appointed manager of the Phoenix mine, Cornwall.

THOMAS F. COLE, of Duluth, president of North Butte Mining Co., has been on a visit to Butte.

THOMAS T. READ attended the meeting of the Geological Society of America at Princeton last week.

JAMES WOOD has resigned as superintendent of the Calumet & Arizona smelter to retire from active work.

F. B. FORBES left last Saturday for Nicaragua, to accept a position at the Escandalo mine, with F. A. Pellas & Company.

A. P. BUSSY, Jr., general manager for the Penn Mining Co., of Campo Seco, has been making a visit to the Arizona copper districts.

D. W. OHERN has resigned as director of the Geological Survey of Oklahoma, and C. W. SHANNON has been appointed to the position.

FREDERICK G. LASIER will be at Crescent City, Florida, during January and February, returning to Detroit, Michigan, early in March.

S. F. SHAW, superintendent for the American Smelting & Refining Co., at Charcas, San Luis Potosi, is spending the holidays at San Antonio.

H. A. GUESS has been made consulting engineer for the American Smelting & Refining Co., and will hereafter be at 165 Broadway, New York City.

WILLIAM F. JAHN is superintendent of the new mill and cyanide plant of the New York & Honduras Rosario Mining Co., at San Juancinto, Honduras, Central America.

WILLIAM MALONEY has been appointed Territorial Mine Inspector for Alaska. He will work in coöperation with SUMNER S. SMITH, of the U. S. Bureau of Mines.

D'ARCY WEATHERBE has been appointed consulting engineer for the Casey Cobalt, Cobalt Townsite, and other Canadian mines controlled by a financial group in London.

L. MAURICE COCKEREL, from Guanajuato, W. S. HARRISON, of the San Francisco del Oro, and J. LESLIE MENNELL, from Mexico City, are among the arrivals in London from Mexico.

U. A. GARRED, superintendent of construction at the Washoe Reduction Works, Anaconda, has resigned and will go to the Mount Morgan Gold Mining Co., Queensland. W. N. TANNER will succeed Mr. Garred at Anaconda.

H. M. WOLFFIN, one of the engineers of the United States Bureau of Mines, has been detailed for work in California in connection with the Industrial Accidents Commission. His work will be directed to increasing safety in the mines.

Obituary

JOHN J. CRAWFORD, former State Mineralogist of California, died suddenly of heart failure at the Key Route station, at South Berkeley, January 7.

M. A. MCALL, for a number of years managing director of the St. John del Rey Mining Co., Ltd., died in London on December 6.

The Metal Markets

LOCAL METAL PRICES

San Francisco, January 8.

| | | |
|---|------|---------|
| Antimony | 9 | — 9½c |
| Electrolytic copper | 15½ | — 15¾c |
| Pig lead | 4.40 | — 5.35 |

| Tin | 41 | — 42½c |
| Spelter | 6½ | — 6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 7.—The copper market is weak and there is but little demand being evidenced; lead remains dull, and spelter is weak. The stock transactions on the New York Stock Exchange for the year 1913 amounted to only 83,362,639 shares, which is the smallest reported since the year 1897, when the sales totaled 77,177,132 shares. January copper is offered at 14.37½; February, March, and April, at 14.30; and electrolytic at 14.62½c. The tin market is easy with spot and January at 36.50 to 36.70. Antimony is dull, with Cookson's quoted at 7.45 to 7.60.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| per ounce, 31 mils silver. | | Average week ending. | |

| June | 17.23 | 14.71 | Dec. | 17.37 | 14.25 |

Owing to the 'hang-over' of the advance during Christmas week, the copper market was firm at the beginning of last week and good sales were made. It was reported that several of the large sellers had no more January copper on hand.

There is a large amount of February copper still to sell, however. The rest of the week the market was inactive, waiting for the fortnightly statistics from abroad and the Producers' figures. Exports for December were 30,503 tons, as compared with 29,274 in 1912. The foreign statistics to December 30 showed an increase in stocks and the visible supply. As the Producers' figures are expected to show an increase in the stocks here, there is not likely to be much buying until after they appear.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Dec. 11 | Dec. 18 | Dec. 24 | Dec. 31 |
|-------------|---------|---------|---------|---------|
| | 40.00 | 40.00 | 40.00 | 40.00 |
| | | | Jan. 8 | 39.50 |

Monthly averages.

| | 1912. | 1913. | | 1912. | 1913. |
|------|-------|-------|-------|-------|-------|
| Jan. | 43.75 | 39.37 | July | 43.00 | 41.00 |
| Feb. | 46.00 | 41.00 | Aug. | 42.50 | 40.50 |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, January 8, shows an increase in production and stocks on hand. The details are as follows:

| | Pounds. |
|--|-------------|
| Stocks of marketable copper of all kinds on hand at all points in the United States, December 1, 1913... | 47,929,429 |
| Production of marketable copper in the United States from all domestic and foreign sources during December | 138,990,421 |
| Deliveries for consumption, December | 21,938,570 |
| Deliveries for export, December | 13,542,413 |
| Stock of marketable copper of all kinds on hand and at all points in the U. S., January 1 | 91,438,867 |
| Recent changes in surplus have been as follows, in pounds: | |
| | Increase. |
| December 1912 | 19,148,523 |
| January 1913 | 17,885,770 |
| February | 896,134 |
| March | 18,032,928 |
| April | 28,720,162 |
| May | 8,074,883 |
| June | 14,769,619 |
| July | 690,330 |
| August | 15,280,908 |
| September | 8,531,043 |
| October | 2,773,288 |
| November | 15,363,047 |

| Commodore..... | 1,000,000 | Kinney..... | 500,000 |

MINERAL OUTPUT OF JAPAN

According to statistics compiled by the Department of Agriculture and Commerce, the output during the last fiscal year was valued at \$65,120,667, an increase of \$12,155,909 compared with the previous year. The principal minerals were as follows:

| Mineral. | Quantity. | Value. |
|-------------------------|-------------|--------------|
| Coal, tons..... | 19,659,755 | \$30,705,918 |
| Copper, pounds..... | 138,711,322 | 20,126,645 |
| Gold, ounces..... | 165,952 | 3,399,524 |
| Iron, short tons..... | 76,301 | 1,535,151 |
| Petroleum, barrels..... | 1,388,853 | 4,188,536 |
| Silver, ounces..... | 4,832,850 | 2,948,042 |
| Sulphur, tons..... | 60,615 | 686,421 |
| Zinc ore, tons..... | 39,364 | 549,063 |

GOLD OUTPUT OF WESTERN AUSTRALIA

During October 1913, the mines of the state produced 111,508 fine ounces, the following being some of the principal yields:

| Mine. | Tons. | Yield. | Profit |
|--------------------------|--------|-----------|----------|
| Associated..... | 11,368 | \$ 68,000 | \$ 7,500 |

Company Reports

LENA GOLDFIELDS, LIMITED

This Company controls large placer deposits in Siberia, and the report covers the year ended September 30, 1913. During the year revenue amounted to £672,499, made up of £81,270 cash balance from the previous term, £378,664 from Lenskoie Gold Mines Co.'s shares sold, £178,629 from Lenskoie dividend, and £33,936 from interest and royalties. The Lena Goldfields paid £266,648 in dividends, etc., and has a cash balance at September 30 of £405,851. The Company holds 61.20% of the Lenskoie company's stock. The Lenskoie, the operating company, mined 820,189 cu. yd. of gravel, yielding 335,348 oz. gold, against 549,244 cu. yd. and 260,505 oz. gold in the previous year. The total production of the different groups of claims since the commencement of operations is 4,746,511 oz. gold, as given in the report of Charles M. Rolker. Out of 950 drill-holes, 69 average over 7 dwf. per yard. Probable reserves are as follows: stream length, 30,275 ft.; gravel content, 2,438,424 cu. yd.; total gold content, 946,230 oz.; net profit, 187,003 oz. Doubtful reserves have a stream length of 15,687 ft., containing 682,722 cu. yd. of gravel and 180,714 oz. gold, on which there would be a loss of 24,266 ounces.

YUANMI GOLD MINES, LIMITED

This Company operates the Yuanmi and Oroya Black Range mines, in the East Murchison goldfield, Western Australia. Operations during the year ended June 30, 1913 were as follows:

| | |
|-------------------------|-----------|
| Yuanmi mine: | |
| Ore reserves, tons | 71,391 |
| Ore milled, tons | 64,530 |
| Gold recovered | \$528,000 |
| Profit | 307,000 |
| Oroya Black Range mine: | |
| Ore reserves, tons | 45,377 |
| Ore milled, tons | 59,680 |
| Gold recovered | \$525,000 |
| Profit | 307,000 |
| Dividends | 212,000 |

ON THE BEHAVIOR OF COLD ACID SULPHATE SOLUTIONS OF COPPER, SILVER, AND GOLD WITH ALKALINE EXTRACTS OF METALLIC SULPHIDES. By Frank F. Grout. Reprinted from *Economic Geology*, August 1913. P. 26. An investigation by laboratory experiments, simulating natural conditions, of the conditions by which secondary sulphides may be deposited. The author finds that metallic gold, silver, and copper may be precipitated from acid sulphate solutions, but rarely the sulphides of the metals. From his experiments he concludes that the secondary sulphides of these metals may be precipitated from descending acid solutions in a zone where alkaline solutions predominate and the two mingle.

OFFICIAL YEAR-BOOK OF THE COMMONWEALTH OF AUSTRALIA.

Compiled by G. H. Knibbs. No. 6, 1913. P. 1236. Ill., maps, charts, index. Commonwealth Bureau of Census and Statistics, Melbourne, Victoria. This is a valuable publication, containing authoritative statistics for the period 1901 to 1912, inclusive, and corrected figures for the period 1788 to 1900. It is not merely a record of statistics in tabulated form, but contains a considerable amount of interesting details of everything connected with the work of 4,800,000 people on an area of 2,974,581 square miles, mining being well covered. The price of this book, including postage and duty, is about \$1.75.

Decisions Relating to Mining

OIL LEASE—NO FORFEITURE CLAUSE

An oil and gas lease binding the lessee to drill a well on the leased premises within a certain period, or in lieu thereof make periodical payments of rental or delay money, and containing no clause of forfeiture, is not forfeitable merely by non-payment of the rental. It can be terminated only by surrender, abandonment, or expiration of the lease.

Reserve Gas Co. v. Carbon Black Mfg. Co. (West Virginia), 79 Southeastern, 1002. September 30, 1913.

OIL LANDS—INJUNCTION DENIED

Where in an action to enjoin defendants from operating for oil on land, it appeared that they had been in undisputed possession for a number of years, had drilled a number of wells, built tanks, established pipe-lines, and produced large quantities of oil, a preliminary injunction was properly dissolved.

Ingram v. Bream (Pennsylvania), 88 Atlantic, 880. June 27, 1913.

COAL LANDS—SUIT FOR RESCISSION OF SALE

The grantee of coal in place under a deed conveying all the coal in a tract of land cannot rescind the sale merely because the coal area in the land is not as large as he had expected to obtain or because a particular vein which he had expected to find there was missing, but he may retain a repayment of so much of the purchase price as equals the value of any shortage in the acreage contracted for.

Light v. Grant & Co. (West Virginia), 79 Southeastern, 1011.

SOAPSTONE LEDGE—NO ADVERSE POSSESSION

A grant to 'G and his assigns' of the right to mine minerals created only a life estate in the grantee. One accepting possession of land under a deed reserving the mineral rights above granted could not establish adverse possession to the soapstone ledge involved by merely building a fence around the entire tract, as such act was not in itself adverse to the mineral grantee.

White v. Shippee (Massachusetts), 102 Northwestern, 948. October 22, 1913.

DAMAGES FOR UNLAWFUL REMOVAL OF COAL

The measure of damages for a surface tenant's unauthorized mining of coal is the value of the coal in place, where there is evidence to show such value, and not its value at the pit's mouth. Where the mine is immediately available for operation and there is a present market, such value is the royalty value, otherwise value in its natural state. Treble damages should not be awarded where the coal was removed by mistake, honestly or unintentionally made.

Trustees v. Lehigh Valley Coal Co. (Pennsylvania), 88 Atlantic, 768. June 27, 1913.

To the same effect see:

Stark v. Pennsylvania Coal Co. (Pennsylvania), 88 Atlantic, 770. June 27, 1913.

Belt Conveyors

The use of these is extending in every branch of mining and metallurgy. These include the handling of ore underground, from crushers to ore-bins, from bins to various types of grinding machines, disposing of mill residue on high dumps, stacking dredge tailing, and handling coal and any material necessary, where other conveying machinery is not suitable. The wear and tear on belts in some works is extremely heavy, and only the best rubber construction will stand it.

The accompanying photograph shows a 'Longlife' conveyor-belt built by the B. F. Goodrich Co., at Akron, Ohio. This belt, which is to be used in handling coal, is 1322½ ft. long and 36 in. wide. It is of 7-ply construction, with a 3/16-in. top rubber cover, and weighs over 14,000 lb. net. In order to handle it during shipment, it was necessary to divide it into two parts, but it will be used on one conveyor. The Goodrich factory is the largest of its kind in the world, and its belt room is likewise the greatest in size and capacity. Transmission, elevator, and conveyor-belts, ranging from the

A 14,000-LB. BELT.

smallest transmission to 72-in. conveyors, can be turned out at the rate of approximately four miles per day. This great production has enabled the Goodrich factory to effect many manufacturing economies, and to offer service which has been the subject of much favorable comment. Shipments are being made constantly to all parts of the world, and Goodrich belts, especially 'Longlife' conveyor, are to be found in mines and plants everywhere.

Mine-Rescue Telephones

One of the important additions to the work which is being conducted to bring about safety for mine workers has been the perfection of a mine rescue telephone equipment. Rescue crews, although equipped with oxygen helmets and various safety appliances, have heretofore been considerably hampered in their work by the lack of means of communication with the outside of the mine. The mine rescue telephone equipment manufactured by the Western Electric Co. consists of a transmitter which is arranged to fit the throat of the helmet man, thus permitting of the transmission of the sound waves through the walls of the throat, as the mouth is needed for breathing the oxygen. A head receiver is also furnished, the combination of receiver and transmitter being held in place by a light but serviceable leather harness. The helmet man also carries one or more coils of wire, which connect to the telephone at the mouth of the mine. This wire pays out as the rescue gang advances. The advent of mine-rescue telephones in safety work is an important step forward and a much larger use is anticipated in the future.

Commercial Paragraphs

The Westinghouse Electric & Manufacturing Co. has undertaken a number of contracts during the past year for hydro-electric development in Alaska. The most important of these is the new generating unit for the Alaska Treadwell Gold Mining Co. to be installed in the Nugget Creek Development. This unit will consist of a 2350-kva. water-wheel generator driven by a Pelton water-wheel running at 300 revolutions per minute, and will give the mining company about 3000 additional horse-power. A 50-kw. motor generator exciter set with special shaft so that the unit may be driven by water-wheel when desired, is also included. A contract has also been recently closed for a 300-kva. water-wheel generator to be installed by the Chichagoff Mining Co. near Sitka. This generator will be used to supplement the Company's present installation, which is 127½ kw. With the generator in question there were also ordered the necessary step-up and step-down transformers for transmitting the energy at high voltage from the power plant to the mines. During the summer the Kennecott Mines Co., operating one of the highest grade copper mines in the world, in the Copper River district, purchased a 200-kva. water-wheel generator, together with all the necessary switch-board and accessories. This water power-plant will supplement a steam driven power-plant now being operated by the Company. A considerable number of electric motors for mining and milling operations were purchased with the above generators. In addition to the above, the Alaska Juneau Gold Mining Co. of Juneau, Alaska, recently purchased from the Westinghouse Electric & Manufacturing Co. a 1012-kva. water-wheel generator to be driven by a Pelton wheel, the energy from which will be used to supplement that of a 937-kva. steam turbine.

Catalogues Received

CHICAGO PNEUMATIC TOOL CO., Chicago, Illinois. Bulletin No. 149. 'Chicago Portable Mine Hoist.' 8 pages. 6 by 9 inches. Illustrated.

ALBERGER PUMP AND CONDENSER CO., Newburgh, New York. Bulletin No. 18. 'Alberger Spiroflo Surface Condensers.' 32 pages. 6 by 9 inches. Illustrated. This deals with the 'Spiroflo' condenser, rotative dry air pumps, 'hydroflo' pumps circulating pumps, and cooling towers.

INGERSOLL-RAND CO., New York. Form 672. 'Story of the Imperial.' 9 by 12 inches. Illustrated. This attractive publication describes the main points in design and construction in the 'Imperial' air-compressors. Those using, or about to use compressors should study this valuable book.

DODGE MANUFACTURING CO., Mishawaka, Indiana. Catalogue 106-A 14. 'Power Transmission Machinery.' 98 pages. 6 by 9 inches. Illustrated. This is an interesting publication, covering such information as horse-power of shafting, key seating, inconsiderable detail, flange couplings, hangers and bearings, ring-oiling pillow blocks, tighteners, friction clutches, Dodge wood-split pulleys, iron-split pulleys, gears, ropes, and belts. Prices are also given for each article mentioned.

NEW YORK ENGINEERING CO., New York. Catalogue 'G.' 'Empire Prospecting Drill.' 46 pages. 7 by 10 inches. Illustrated. Increased attention is being paid to gravel deposits containing gold and tin in remote parts of the world, and a handy prospecting drill is a prime necessity. This handsome publication, besides giving details of the machine, illustrates their use in Canada, Korea, Colombia, Cornwall, Brazil, Siberia, Manchuria, Russia, and the Philippines. There are also descriptions of the pulling level, casing pulling jack, drilling winch, casing, cleaning bedrock, and a clean-up and assay outfit. A few pages are devoted to dredges and mechanical elevators.

EDITORIAL

IN spite of the statement made by the President some time ago to the effect that no movement would be made by the army or navy which would convey the impression that preparation was being made for hostilities in Mexico, and regardless of the fact that the permission granted by the Mexican government for American warships to remain in Mexican waters expired some time ago, there are fifteen warships off the Mexican coast and a fair sized army encamped along the Rio Grande.

SAFETY first has found a new expression in Nevada through the passage of a law, which went into effect the first of the year, prohibiting the employment of men in and about mines who cannot speak or understand the English language. An industrial safety conference has also been organized for promoting the safety first movement, which will convene at Reno on January 26 and 27. The Governor, Mr. Tasker L. Oddie, will preside at the conference and a number of papers have been prepared which will treat the various phases of the movement.

ANNOUNCEMENT is made of the appointment of Mr. R. W. Brock to the position of Deputy Minister of Mines for Canada, a position in which he succeeds Mr. A. P. Low, for whom he has been acting some years. This is an eminently fitting recognition of good work not only in geology but administration, and Canadian mining men are to be congratulated on having so able and sympathetic a representative in this high position. Under the form of government obtaining in Canada the Deputy Minister is a non-political permanent officer. As such he becomes the technical adviser of each succeeding Minister. Mr. Brock will have charge of both the Geological Survey, of which he is director, and the Mines Branch of the Department of Mines.

ARRIVAL of the steamship, or more properly the motor ship, *Siam* in San Francisco recently marks the advent of a new type of marine boat in these waters. Equipped with modern Diesel type engines, this 13,000 ton freighter, using 20 tons of oil a day in its internal-combustion engines, and with a sailing radius of two months, has demonstrated the wide adaptability of crude oil fuel to marine purposes. The sixteen cylinders of the *Siam* power-plant develop 3200 horse-power at a fuel cost of about two cents per horse-

power day, which is in marked contrast with the eight and ten-cent costs of the boiler and steam engine type of ships. The cargo capacity is also increased by 15 to 20 per cent because of the space saved in boiler rooms and coal bunkers, and this is reflected in lower operating charges.

DETAILS of the world's production of gold and silver for the calendar year 1912, as compiled by Mr. George E. Roberts, director of the Mint at Washington, are presented on another page of the current issue. In the production of gold the Transvaal, as usual, takes first place with a production valued at \$188,293,100; the United States ranks second with a production of \$93,451,500; and Australasia third with a production of \$54,509,400. In the production of silver, Mexico stands first, regardless of the handicap under which mining has been conducted, the output being 74,640,300 ounces. The United States is second with a production of 63,766,800 ounces, and Canada third with a production of 31,625,451 ounces. The world's production of gold was valued at \$466,136,100, while the silver output amounted to 224,310,654 ounces.

ARGUMENT in the Kennedy Extension-Argonaut case was heard at Jackson, California, last week, and upon completion of the record by the stenographer, will be formally submitted to the court for judgment. Interesting as the case is, we forbear comment at this time, the matter being still before the court. We may say, however, that the differences of opinion, as reflected in the arguments of Messrs. G. O. Perry and Frank Zelinsky for the plaintiff and C. H. Lindley for the defendant, relate mainly to the facts. There was practically no controversy as to the law, and only one point of general interest, that is the presumptions allowable from patent issued under the law of 1871 in cases where the location itself was long anterior and allegations in the patent brief. As to the facts, the differences related to the integrity of the apices of the Pioneer and the Jackson veins and their continuity and identity in depth. The question of most general interest to geologists is whether the Mother Lode represents, as previously held by Mr. F. L. Ransome, and as maintained by Messrs. A. C. Lawson, Walter Wiley, and Fred Searls, a thrust fault, or whether Messrs. J. W. Finch and R. D. George are correct in inferring a large normal fault. Of this we shall speak later.

GAS and oil engines as economic sources of power are becoming more universally recognized and their various applications, from turning the farmer's grindstone to the propeller shaft of 10,000-ton freighters, evidence their wide range of adaptability. In Montana the economy of hydro-electric power and the futility of steam-power competition when hydro-electric is available has been proved by experience, and the electrification of a number of the railroads and most of the mines is now under way. Our Butte correspondent points out the tendency toward the development of

electric power from gas engine power-plants at the coal mines. Under some conditions electricity is cheaper to transport than coal, and the thermal efficiency of the internal-combustion engine is far greater than that of the coal-fired boiler and steam engine. There can be little doubt that a large field exists for central power stations in the coalfields, though the proper limits for such practice are not yet determined. It is even possible that the prediction that the Miocene lignites of western Montana will supply power throughout the state may some day be fulfilled, though this is not probable at present. The use of producer gas in Western Australia is recorded in the current edition, and in other parts of the world its success has been amply attested.

California Miners and Workingmen's Compensation

Workingmen's compensation acts have been recently passed in a number of states and, along with the financial adjustment now under way throughout the world, employers are being called upon to reorganize their business upon a new basis with difficulties as great as a general increase in wages. However much we may approve the general principle that each industry should amply provide for its own killed and injured, and the *Mining and Scientific Press* does heartily approve that principle, no one can blink the fact that an increased expenditure equivalent to 27½ cents per day per worker and amounting yearly to 12¾ per cent of the capital of the employing company, these being figures from an actual case, calls for serious question. It is possible that this heavy tax on industry is necessary, and that corresponding benefits will be realized, but we are frank to say that we doubt it, and in any event it will require a complete recasting of wage scales and other elements of cost, with such readjustment of prices as may be possible. The particular illustration taken is that of a gold mine in California. In another case a company which is not yet 'out of the woods' in the payment for its property, must face an immediate increase of payroll of about \$400 per month. Such figures warrant one in pausing to inquire whether our sympathies have by chance outrun our business sense, or whether our employers are being unfairly treated by the insurance companies.

The English compensation act has long been held up as a general model. Figures carefully compiled by a competent commission in Illinois showed that for a term of years all workmen injured in that state might have received compensation under the terms of the law, and yet the total paid would have been no greater than the cost of the old indemnity insurance. Under this condition it was manifestly good sense and good business to pay the money to the workmen rather than expend it on agents' fees and litigation. In the various Australian states there are stringent compensation laws. They must be satisfactory to the laboring men, as they were enacted by labor governments; yet at one large mine in New South Wales, where figures are avail-

able, the cost of insurance is only $1\frac{1}{2}$ per cent of the payroll. In Nevada, where a new law is in operation, the basal rate in mining is $2\frac{1}{2}$ and the maximum is 3 per cent. In California the basal rate is 7.86 and in certain kinds of mines 9.80. The lowest mining rate scheduled in California, that for prospecting, is 6.75. It is true that private insurance companies have, in some cases, allowed separate classification of surface men in such manner as to bring the average down to 5 per cent, but even this is out of all proportion to rates paid elsewhere. In other schedules than mining there are similar rates which on their face seem absurdly high, and which will require much argument to justify. The schedules are inconsistent; for example, why should iron mining take a rate of 9.80 and copper mining 7.86? Both are too high, but why are they different?

When the California law was enacted it was part of the plan to insure reasonable rates by having the state itself undertake to carry insurance at cost. In practice something seems to have gone wrong. The total amount of the insurance fund placed at the disposal of the Industrial Accident Commission, which must administer this law, was \$100,000. Premiums to the amount of \$200,000 were reported to have been collected in the first ten days, but clearly an insurance company working on so small a capital is not a serious factor in the situation and its effect on rates is not yet apparent. At first the state refused to accept any individual mining risk of more than \$15,000. Later it was cut to \$10,000. Insurance to that amount is not much comfort to a manager who must face unlimited liability. Few companies would be forced into bankruptcy by a loss of \$10,000 or \$15,000, but many California companies might well be put out of business by a single accident, even after having paid the state premiums upon the total amount of the insurance that the latter will accept. In other words, the mining companies are forced at present to deal with private insurance companies regardless of cost. Only a concern with a large surplus can afford to carry its own risk. We do not believe that this condition can or will last. The harvest of agents' commissions in the past few weeks has attracted attention throughout the insurance world and there will undoubtedly be increased competition for the California business. We know already of one large London company which is investigating the field.

The reason urged for the high rates in California is that the liability is unlimited. A man totally injured is to receive a pension for life, and in similar details there is a large and unmeasured risk not met under the laws of other states. There should be some way to meet this situation. It is always possible to commute an annuity, and a way will doubtless be found to convert into lump sum settlements these contingent risks. In Nevada the maximum individual payment is \$5000, and we see no reason why more should be paid in California. If the workman wants more insurance he

can buy it at current rates for himself. California industries do not stand alone. In gold mining the selling price cannot be raised, and in cement making and other competitive industries it is equally impossible for the operators in one state to raise their prices generally. All that can be done by the manager facing such a situation is to raise the price to the limit in his non-competitive territory, which is that nearest his own works. If the rates now quoted are really the best warranted under the law, the latter should be promptly modified, since protection ample elsewhere is certainly sufficient in California.

In New York there has recently been enacted a law which is hailed by Mr. Samuel Gompers as the best yet put on the statute book. It also meets the approval of so sturdy a champion of capital as the *New York Sun*, and those who are responsible for it seem to have accomplished the difficult task of pleasing both sides. It is possible that the pleasure may be more one-sided after the law has been subjected to a test in the courts. The measure provides for the usual commission, but gives it the unusual power of bringing suit, at state expense, against any employer who does not pay the compensation due. The employee is debarred from bringing suit. The employer may insure himself with the state, or some company, may join in forming a mutual association, or may, where his resources are ample, carry his own risk. An injured employee, after a waiting period of two weeks, receives two-thirds wages. In the case of permanent partial disability he receives two-thirds the amount in wages lost as a result of the injury. The widow of a man killed receives 30 per cent of his wages during her widowhood, with 10 per cent additional for each child under 18 years of age, the total not to exceed $66\frac{2}{3}$ per cent. This law is cited to indicate that the California plan is not necessarily the only satisfactory one.

In commenting on the situation faced by California mine managers, we would not be understood as criticising the commission charged with the administration of the law. As business men its members cannot assume risks beyond those warranted by the capital advanced by the state, and we have no doubt that they will use every proper effort to secure as low rates as may be possible. We commend unreservedly their action in organizing the safety department. A determined effort has been made to get the best men available, and for the mining work, the United States Bureau of Mines has, by request, detailed Mr. H. M. Wolfen, a capable and experienced mining engineer. This is the more commendable since in certain other branches of the state's activities politics has been permitted to dictate appointments as our readers know. Also the exemption of farmers from the provisions of so general and so sweeping a compensation act as that of California, is a transparent appeal to political favor. We are entirely unable to see why a man is less dead when killed by falling off a haystack than down a winze, or how his widow is less of a problem.

What is the Matter With Prospecting?—II

A SYMPOSIUM

In the annual review number we published a number of letters received in response to the inquiry sent to many of our friends prominent in mining circles, regarding the evident lack of interest in prospects and the apparent dearth of funds available for prospecting purposes. We find the mining fraternity is greatly interested in this subject and take pleasure in presenting this series of extracts from the numerous letters which have been received.

R. Gilman Brown:—I cannot speak for conditions in the United States, but so far as London goes there are several venture companies here who devote a good deal of expense to developing prospects. As to finding prospects, that is a difficult matter for a company to embark in; at the same time I know of more than one London syndicate that has sent out men into promising regions. Looking at this from another angle, there are several companies in England owning large tracts of country abroad, supposed to be mineralized, that have been successful in carrying on organized and scientific prospecting within their areas, maintaining specifically a geological and prospecting staff for this purpose. I can cite the Ashanti Goldfields as one of these companies, whose prospecting work, under the scientific management of Mr. Justice, has already resulted in the discovery of Justice's Find. The Kyshtim Corporation, under American geologists has been doing the same work successfully in the Middle Urals, Russia; and the Tanalyk Corporation has been working on similar lines in the Southern Urals. All of the above companies, and I think most companies of this class, have had as a basis, discovered mines which they were either developing or operating. I rather tend to the belief that in order to justify the risking of capital in prospecting work, the general control of it should be under a trained geologist. This does not eliminate the prospector, but merely puts a man over him. I do not believe in direct government aid for anything: indirect aid could perhaps be supplied by opportunities to take up prospecting licenses in certain areas on liberal terms as to the ground that can be acquired under them, and with suitable provisions to prevent large areas of ground being held and not prospected. I am strongly of opinion that prospecting methods can be vastly improved, waste work eliminated, and fewer good opportunities lost, by expert geological control. If by "undeveloped mineral lands" you mean lands on which promising surface indications have been found, but little more than trenching done, I would say that here again the practical geologist comes in, and so far as my own companies go we have not hesitated to spend money in investigations when our geologist in charge has given favorable reports. In general, it seems to me evident, that as the more easily recogniza-

ble and more accessible deposits are found, prospecting work is bound to become more expensive, involving shaft-sinking, drilling, etc., and that consequently the scope for the 'grubstake prospector' is being limited.

L. S. Cates:—During recent years two conditions have arisen which I think will answer practically all of your questions: The first is, the change in the class of men who are following the mining business. The old time prospector, such as was in existence twenty years ago, is almost a thing of the past. There are very few men who have the disposition which will allow them to isolate themselves from civilization and endure the hardships which are necessary to those who enter unexplored portions of our mining territory. This may be caused by the change in the early education of the present generation, or from the fact that employment is so easily obtained by those who desire to follow the mining profession. At the present time there are so many large camps developed that a man can usually obtain employment very easily, whereas, in the past when there were only a few camps it became profitable and necessary during certain portions of the year for a man to devote a portion of his time in prospecting. Personally, I do not think there is any ground for the statement that there is no money available for grub-stake. The real trouble lies, as has been mentioned before, in the fact that it is hard to find men who will conscientiously and intelligently spend time and money in looking for new mines. The second condition, which has arisen during recent times, is the appearance of the unscrupulous mine-promoter. There is hardly a city or town in the United States which has not been visited by this character. In a great many instances, he knows nothing regarding mining and spends a major portion of his time traveling from one town to another selling cheap mining stocks and putting ridiculous advertisements in the papers, in an attempt to further their unworthy endeavors. This has been going on for such a long time, and so many people have been fraudulently deceived into placing their earnings in these wild-cat adventures, that the public at large is being gradually educated and looks askance when one mentions the subject of mining investments. I must admit that a great many excellent properties have been developed from prospects to productive mines in this manner, but the majority of the money raised has been ruthlessly squandered. Another reason why undeveloped claims are not attractive is because the larger interests prefer to pay a large sum for a developed property than to take a prospect and endeavor to make a mine from it. However, I think eventually this policy will have to be changed. Owing to the old prospector being a thing of the past and the small investor refusing to assist in

the development of the minor properties, it will become necessary for the larger interests to organize and maintain exploration departments, but just how long it will be before this condition will materialize is problematical.

John Wellington Finch:—I do not find it true that money is no longer available for developing prospects. I am at the present time engaged in the supervision of the development of a number of prospects which are being opened up under lease and bond arrangements by experienced mining people. It is true, however, that none of the operators with whom I am associated consider it wise to expend money for finding prospects. Perhaps they are guided to some extent by my advice in this matter. Additional money for such purposes is becoming available automatically, because there is an increasing number of owners of prospects who are willing to share the chances of exploitation with the purchaser by offering their properties under reasonable terms as to time and payments. I do believe in Government aid to prospecting and prospectors. I think this aid can best be given by allowing them the freedom of the public domain for their explorations and by eliminating all unreasonable obstructions. Prospecting methods are, in my opinion, all right as they are. The natural person to discover new mineral deposits is the man who can subsist simply and who has the physical endurance and patience to wander for long periods of time in remote places. Such a man is usually a miner and not an engineer. He is bound to locate valueless deposits along with the occasional deposits of prospective merit, but he does sufficient work upon the latter so that the man of higher training and more fastidious physical requirements may find a sufficient basis eventually to interest the capital which he represents. At the present time very little actual prospecting is being done because the prospecting miner has been so mystified by the restrictions placed upon him by some of the governmental bureaus that he is reluctant to expend his efforts in searching for that which he afterward may find he is not allowed to possess as he did in former times, when he was permitted to explore upon all lands owned by the Government. The chief trouble with the restrictions and supervision now imposed by the Government is, it seems to me, not so much that the supervision is improper but that it is not uniform, nor is it clearly defined. Prospecting would, I believe, be gradually resumed if the prospector could clearly comprehend the regulations under which he must act and could feel sure that mineral locations would not be taken from him by the whim of individual Government agents not technically qualified to pass upon the merits of the location. I consider the market for undeveloped mineral lands to be good, on the whole. The development of new coal areas is, of course, not likely to be undertaken until capital can be satisfied that it will be allowed to work tracts of sufficient size to give the enterprise long enough life to make it attractive. Nor

will new coal lands be worked under the leasing system until the commercial possibilities in it, from the point of view of the lessee, can be clearly calculated. In metal mining, I feel quite optimistic concerning the proper future development of promising prospects. The great mining corporations and syndicates are concentrating their attention upon thoroughly developed properties. The promoter, who was once the intermediary between the prospector and capital, is not now able successfully to present prospects to these concerns. Moreover, the prosecutions by the Department of Justice have curtailed the activities of the unscrupulous promoter in the use of the mails. This form of promotion has been the chief cause of exorbitant prices for prospects. In several instances with which I have been familiar in the past year, enterprising small mining companies have been able to acquire prospects on businesslike terms whereby the original owner and the purchaser became joint owners in such a way that a successful outcome of development would inure to the benefit of both.

G. W. Metcalfe:—In my opinion, the money available for finding and developing prospects is strictly proportionate to the probability of making a profit from such investment. This particular district, Shasta county, California, is largely a copper district. Even when a promising copper prospect is found, it takes a large amount of money to develop it to the point at which it is possible to determine its value. In addition to the ordinary risk in prospecting, the prospector also has to consider that if he finds a copper mine of sufficient magnitude to justify the construction of a smelter, the present attitude of the Legislature and of many agriculturists is decidedly inimical toward allowing him to operate such a smelter if the slightest indication can be found of any effect from his smelter fumes on vegetation, even although such effect does not amount to material damage. This consideration has been extremely discouraging to copper prospecting in this district. Another difficulty in this district is the fact that a large quantity of land in the copper belt is the property of the Southern Pacific Railroad. The prospector is likely to find, in case he discovers a mine, that it is on railroad land and that there is no way in which he can obtain any advantage from his discovery. In general, I think the only way that more money can be made available for prospecting is for conditions to change so that the probable returns from such investment would be larger than at present. I do not believe in government aid to prospecting and prospectors in any very radically different way from that in which such aid is now being supplied; that is to say, the government has made and is making a geological survey of the country, which survey, when completed, will give much information as to where it is reasonable to look for mineral deposits. The state government of this and other states maintains mining schools in which embryo mining engineers are given the training which should enable them most readily to

take advantage of the further lessons they will receive from experience. These and similar activities on the part of the government are perfectly proper and very valuable. The available funds for prospecting appear to be adequate; that is to say, the inducement at present for prospecting appears to be great enough, so that sufficient supplies of the valuable metals are discovered to supply the world's needs. If the possible metal famine actually comes to pass, the price of metals will naturally rise to the point at which greater returns can reasonably be expected from an investment in prospecting or mining. When this occurs, there will be a greater inducement than at present for the investing of time or money in prospecting work, with the natural effect that more mines will be found and developed and the metal famine will be a thing of the past.

E. H. Nutter:—The nomadic prospector, with his shovel, pick, pan, and a sack of grub, on a burro, is largely of the past. Can he be revived, and is it worth doing? I think not. This old-time prospector, who found most, if not all, of the productive districts, was, I think, always animated by the hope of 'striking it rich'; that is, he was on the lookout for rich surface ores of gold, silver, lead, or copper that would pay for burro-back transportation, or reduction by the sluice, arrastre, or other primitive device, hoping, as well, to find something that he might sell at a good price. Spurred by this hope, he did a great deal of burrowing or gophering in likely looking places. A large part of his effort was wasted; the rest opened up or drew attention to the mines or districts that have become productive, and which attracted capital or produced their own capital. The Klondike excitement drew off a large part of this type of prospector from the older districts and started the condition in them to which your letter draws attention. Except perhaps in British Columbia and other parts of Canada, the continent has been pretty well prospected, and the chances for a prospector of the old type to find rich surface ore or alluvial gold are slimmer than they ever were. In consequence, he is disappearing for lack of subsistence; he cannot make even his modest living, rent-free and tax-free though it is, and a 'grubstake' is not so easy to get now, and fails to satisfy as it once did. So far as my experience with the capitalist goes, he is willing to put up money when there is a good chance of seeing it come back again leading some more with it. He relies more and more on his engineer's advice, if he is not himself an engineer. In general, probably more is lost than gained from putting money into the exploration and development of mere prospects; also, the owner thereof usually asks more than they are worth. There are certain classes of investors, however, who look to mining or collateral branches for investment possibilities rather than to other industries, and any dearth of conservative opportunities along this line will undoubtedly make available more funds for exploration and develop-

ment. It seems probable, however, that these funds in the future will be spent more and more by men working on salary for others. Their prospecting, too, will be guided more and more by geological considerations. It will be more sanely done, and probably will yield a higher average of profitable returns than did the aggregate work of the old-timer. As to government aid, I do not believe in it for prospecting any more than for manufacturing. While some mineral deposits might be developed earlier thereby than in the natural course of events, I think that on balance there would be greater economic loss than gain. Let the government give us just and adequate laws, continue its geological and police work, and leave the mining industry to work out its own problems.

E. G. Spilsbury:—Unquestionably, the spirit of venture which formerly exhibited itself in the outfitting and staking of the old time prospector and sent him into unknown and unexplored territory has practically died with the incentive. Such terra-incognita no longer exists. On the other hand, money is still to be obtained for the development of claims, when sufficient inducement is offered by the owner of these undeveloped claims. The only way increased capital is likely to be attracted to undeveloped properties, would be by means of a well organized propaganda, publishing reliable and accurate information regarding successful ventures along this line. I do not believe in government direct aid to prospecting for minerals any more than I would advocate that the settler on public lands be subsidized by the government to clear and prepare his land and determine what crops it was good for. On the other hand, increased efforts by the U. S. Geological Survey to give accurate information regarding the geology and mineralization of territory not already thoroughly prospected would, when published, furnish an incentive to careful prospecting by trained men sent out by capital for the purpose. The Survey ought to be the pioneer and not the trailer on behind. For unprospected mineral lands there is no market; and there cannot well be one, as there is nothing tangible to offer to capital—not even a title. On the other hand, after mineral has been discovered, the given claims located, and the locator has something to offer, there is always capital available to carry on the development to a point where commercial success can be predicated provided the original discoverer or prospector is willing to share with capital not only the eventual profits, but also the risks which may attend the attaining of these profits. For instance, supposing a prospector has spent a year in a given field and has discovered mineral which he thinks is worth developing. His expenses during the year have been say \$1000: his outfit may have cost him \$500: his time calculated liberally at \$4 a day would amount to say \$1500 more; his investment therefore would be in all \$3000. Now if the investor comes in and furnishes the same amount, he ought to do so only on becoming a partner to the extent of a half interest. When that amount has been spent on

development a re-appraisal of values should be made, and if further capital is required it should be offered the same proportionate advantages. If some such general plan of co-operation were made public and thoroughly understood I think it would prove a great incentive to the development of simple prospects. The reason why capital is apparently so difficult to obtain by prospectors lies in the fact that the owner of the prospect generally wants to realize an unearned profit before he is willing to accept capital on the same basis as his own investment.

Vice President of a large exploration company writes as follows:—A large amount of money is being used continually for finding and developing prospects. As to the adequacy of the amount it is extremely difficult to judge. The facts seem to warrant the belief that the surface deposits and the more easily found rich mines have been discovered; and that, therefore, prospecting for and finding new mines costs materially greater sums than in the past and also necessitates a somewhat wider vision, as the big new mines that have recently been found are mines in which, what is now (through the advance of mining and metallurgical skill) highly profitable ore, was not so very long ago uncommercial mineral. I do not believe in direct government aid to prospecting or prospectors. The aid that the government can give to this class of work is: (1) Passing understandable and adequate mining laws, so insuring the title of claims legally acquired; simplifying the rulings of the Land Office and prohibiting the passage of retroactive legislation and Land Office rulings. (2) In furthering education in the art of recognizing valuable minerals and mineral products. Prospecting, economically conducted, is bound to be a matter for individuals. No corporation can require from its employees the endurance of the hardships which are cheerfully undertaken by the prospector when the gain to be made is his own or to be shared with a few individuals, all of whom are known to him. It depends on how much the individual prospector can be improved in knowledge of commercial mineral products, their occurrence, and the wise expenditure of money, as to whether the available funds will prove adequate to the finding of new mineral deposits or not. My experience tends to show that 95% of the owners of undeveloped mineral properties put an entirely prohibitive price upon their possessions. The value of undeveloped mineral lands is one of the most difficult values to determine, and consequently the imagination and cupidity of their owners have free rein, and the price that they fix for an entirely indefinite value bears no sort of relation to the risk that has to be run. The direction in which I see a chance for an improved market is the realization by the owners of undeveloped mineral land that if they are not willing to take part of the risk, they should ask the people who are willing to put up the capital to develop their property at a price commensurate with the money that has been spent on locating the property.

Montana Metal Production

The total value of gold, silver, copper, lead, and zinc produced by deep and placer mines in Montana in 1913 was somewhat over \$59,000,000, a decrease from \$64,754,615 in 1912, over 8%, according to preliminary estimates of V. C. Heikes, of the United States Geological Survey. Metal prices were slightly less than those of 1912. There was also a large decrease in copper yield and consequently in gold. These were in part offset by a record increase in zinc production and silver output from zinc ores.

The gold yield decreased nearly 12%, the mine figures being \$3,625,235 in 1912 and \$3,194,000 in 1913. There was no great change in the placer output, but a decrease is noted in gold from copper ores and from silicious ores.

An increase of nearly 4% was made in the silver output of the state, the mine figures being 12,731,638 oz. in 1912 and 13,203,000 oz. in 1913. A decrease of about 10% in silver output from Butte copper ores was largely balanced by an unusual increase in silver from lead concentrate and zinc residues from the Butte & Superior mine, which made a notable record the last half of the year. Over 13% of the total value of the state output was that of silver.

The copper output declined about 9%, from 309,738,873 lb., according to mine reports, in 1912, to 280,658,000 lb. in 1913. This last was about 30% less than the output of Arizona, the leading copper producer in 1913.

The lead output increased from 7,446,749 lb. in 1912, according to mine figures, to 8,547,000 lb. in 1913, or nearly 15%. This increase was largely due to shipments of lead concentrates and residues from zinc concentrates from the Butte & Superior mine at Butte.

A record production of recoverable spelter was made from zinc concentrates shipped from Montana mines in 1913. From 26,918,881 lb. of spelter in 1912, the output increased to 85,449,297 lb. in 1913, or 217%. This was largely due to results at the Butte & Superior mine.

Extensive deposits of platinum have been discovered at Wenden, in Westphalia, Germany. Drilling has been done over 500 acres, and 9 holes gave from 0.9 to 1.9 oz. per cubic yard. Over 100 analyses have been made. Plans are being made to begin extracting the metal from the ores. Unlike the platinum found in Russia and other countries, the German deposits are said to contain the metal in the form of an alloy.

Madagascar, an island off the coast of Africa, and owned by France, produced 2,119,571 gm. of gold in 1912, a decrease of 730,473 gm. compared with 1911. The output of graphite is increasing. There are 942 workings, and in 1912 the yield was 5000 tons. This country will soon be a serious competitor of Ceylon in this mineral.

Deep Mine Pumping and Air Lifts

By A. E. CHODZKO

The end of the last century was marked by a decided advance in the art of treatment of metallic ores, and profitable returns have nowadays become available from immense accumulations of low-grade materials, both in natural and artificial shape, hitherto left unproductive owing to the limited paying percentage obtainable through time honored metallurgical processes. The measure of their commercial returns is the product of two factors, quality and quantity, and the immediate consequence of the new discoveries was the necessity of operating on vast amounts of materials. Leaving aside the mountains of discarded tailing that form a familiar foreground at large mining plants, an unprecedented activity became in order in opening up new underground levels at constantly increasing depths: the methods of exploitation had to keep pace with that increment of production, and among them, the problem of pumping is unquestionably one of the most momentous. It again involves two factors, volume and head, the graphical product of which shows a rapid upward trend.

Percolation of water through the freshly opened ground is generally, for natural reasons, enhanced by the depth, and its growing volume must be disposed of against a likewise increasing height of lift, so much so, indeed, that the machinery built for that purpose has gradually become subjected to requirements of unusual severity as to strength, capacity, and endurance. The chances of breakdowns are more numerous, their results are more serious, the repairs are more difficult and expensive, and when one stops to consider that the lives of the underground force, as well as the commercial success of the entire undertaking are essentially dependent upon the continuous and efficient action of pumps, it is soon realized that the importance of this question could not be overestimated.

Any pretense at a description of the modern types of deep mining pumps is beyond the object and the permissible extent of these pages; it could not, moreover, but be a compilation of a number of valuable contributions on the subject, beginning with the highly instructive review prepared by H. C. Behr for the State Mining Bureau in 1896. All of these machines fall, moreover, within the scope of a few remarks of a general nature. No mining reader is likely to contest the statement that a reliable high lift pumping outfit should meet, at least, two requirements: it must be as free as possible, by its design and by its construction, from causes of accidental stoppage; but should this happen, the pump must be able and ready to start up again under all conceivable conditions, namely, when immersed into any depth of water, and however long it has remained inoperative. The flooding of an underground pumping station at the lower

levels must not be considered a problematic accident, but an ever possible and impending occurrence, unless each plant is built in duplicate, and even if it is.

Broadly speaking, the former desideratum applies to all classes of mining, and even other machinery. The latter is more decisive; it forthwith eliminates all pumps driven by steam or by electricity, under the customary methods of installation, that is, the pump and its motor being in free communication with the shaft. As a rule, any station pump adjacent to its motor and placed below the highest water-level liable to be reached in a flooded mine, should be encased in a water-tight reduct or casemate of reinforced concrete, capable of resisting collapse under the maximum head of water. Very exceptionally will it be practicable to maintain a permanent access from the surface to that submarine engine room; this would be an essential requisite to the use of steam, which is, otherwise, unacceptable. But even for want of it, the machinery would at least remain in working condition during the period of inactivity, while protracted immersion spells ruin of an electric motor. Cornish sets and multi-stage centrifugals driven from above would not require that protective fortification. A piston pump, operated by compressed air, may work under water, provided that the exhaust pipe is carried beyond its upper level.

Duplex Direct Acting Pump

As an instance of personal experience, I may quote a duplex direct-acting pump, installed at the 200-ft. level of an inclined shaft, with its exhaust pipe reaching the 100-ft. level for ventilation purposes. The air-compressor at the collar of the shaft was driven by a Pelton wheel, the supply for which was interrupted during a winter night, by the wholesale freezing of the feeding flume. The pump naturally stopped, the water began to rise in the shaft, and before long had reached the 100-ft. level, and so things remained till the following spring, when the compressor was started again; a few moments later, water issuing from the delivery pipe showed that the pump had instantly responded. This, however, was due, first to the unusual extension of the air-exhaust pipe, which is very exceptional in a pump of that kind, and also to the fact that the rapid inrush of water at the time of stopping had caused the attendant to take a bee line toward upper quarters, leaving the throttle at the pump wide open.

It is safe to contend that machinery in motion under water charged with foreign substances, beyond possible control, oiling, etc., is apt to get out of order at any time, and cannot be depended on for steady work. Another drawback common to all high-lift pumps is

that due to the violent vibration of a long column of water in motion under heavy pressure, with consequent leakage and breakdowns. So that, leaving aside the inconvenience of immense moving weights and of a cumbersome and expensive outfit, it is true to say that the old types of pumps driven from the surface were offering better guarantees of permanent action in a deep mine than the more improved underground installations of today.

There is, however, one class of modern pumps enjoying a marked immunity from all the previous objections, and in which compressed air is in immediate contact with the water to be raised. Their principle of action is elementary.

If we have an inverted siphon with two equal branches, one (A) open at its upper end, and the other (B) connected to a supply of water and likewise open, the latter will fill the two branches and occupy the same level in both, placing them in perfect balance. Now, if in any manner we alter the weight of water

in one of the branches, leaving the other intact, a flow will take place from the heavier branch toward the lighter, and therefore if we place a weight at the surface of the water in branch (B) (or which amounts to the same, if we close that branch and admit air under pressure on top of the water) the latter will be forced down in (B) and escape at the top

FIG. 1.

of (A), compressed air replacing in (B) the expelled water. This type of pump is known as a 'displacer.' When branch (B) is full of compressed air, the latter is shut off, and allowed to escape; then a fresh charge of water takes its place, and is again driven out, and so on. The action of the displacer is therefore essentially intermittent, branch (B) being alternately emptied and refilled, and the successive admissions and exhausts of compressed air being regulated by an automatic timing device.

Let us now revert to the original siphon, in its balanced condition, and without touching branch (B), which is open to the water supply, let us admit compressed air by a pipe (c) at the foot of branch (A). This air will rise up that branch by reason of its lesser density, eject part of the water from the pipe by its expansion, and form, with the remaining contents of (A) a mixture lighter than the water alone. The contents of (B) are therefore lighter than those of (A) and a flow will set in, and persist as long as air arrives at (c), the water in (A) being constantly replaced by the supply. This class of pump is the 'Air Lift' proper,

and it is evident that its action is continuous, without the necessity of any timing device.

In practice, the displacer (B) is a closed vessel, communicating with the water supply through an inlet valve which opens automatically when the air has escaped, and with the delivery pipe (A) by a discharge valve, which closes at the same time. In the air lift the branch (B) is represented by the well supplying the water, which enters the delivery pipe (A) at its lower end, where it meets the air pipe.

Both kinds of pumps have been widely used. The displacer is better adapted to mining work because it is more compact and not subject to the condition of acceptable efficiency, of having a submergence practically equal to the actual lift which in a deep shaft would require an abnormally deep sump. On the other hand, the use of a volume of compressed air equal to that of the water raised, and allowed to escape without doing expansive work, reduces considerably the efficiency of the displacer. However, its simplicity and positiveness of action may recommend its adoption in a number of cases for temporary work.

This low efficiency has been improved upon by a combination of the two classes of air-pumps, the submergence head of the air-lift being replaced by an equivalent air pres-

FIG. 2. DISPLACER.

FIG. 3. AIR LIFT.

sure acting by displacement, and the delivery column being made lighter by a separate injection of compressed air. Such is the Starrett pump, which uses an air pressure much lower than would be required in a single displacer, where it must balance the hydrostatic pressure of the discharge column. This pump, which has been tentatively used at the Ward shaft of the Comstock, requires a free exhaust and a timing gear, and its action is consequently intermittent. It escapes to a great extent the main objections to the motor-driven pump, and can operate under water; and while there is no record of its use for a large capacity, it stands at the present time as the only air-lift pump having so far been practically applied to deep mining work.

Air-lifts seem, therefore, to point out a logical direction toward the economical and safe solution of the deep mine pumping problem. A study of this question, extending over several years, and based on former experience with other kinds of air pumps, has led to interesting results which are hereafter briefly presented.

Whatever be the exact behavior of compressed air in raising water up a delivery pipe, it will have yielded all of its useful effect if, in course of the process, it expands from its initial to its final, that is, to atmospheric pressure. Now, if (P_1) is the absolute air pressure (that is, the gauge pressure plus atmospheric) and (P_0) the atmospheric, it is easily found that at any particular place, if the compressed air enters the pump at the same temperature as it entered the compressor, the efficiency (E)—that is, the ratio of the work done by the expansion of the compressed air to the work absorbed in compressing it—is expressed by

$$E = M \left(\frac{P_0}{P_1} \right)^{0.29}$$

when (M) is a numerical factor involving the altitude, and the mechanical efficiencies of compressor and pump.

The conclusion is that a low-pressure air plant is more efficient than a high-pressure one, or, in this particular case, that a low lift is more efficient than a high lift. And, therefore, if water is to be raised to a great height, the idea naturally occurs of cutting this up into a number of shorter divisions, each supplying water to the next one above. This has been suggested as a means of adapting the air-lift to mining work, each division being made longer than the one below, and a great height could thus be reached with a limited number of successive steps, the air pressure increasing from one to another.

A more satisfactory result is obtained by making the subdivisions of equal lengths. The pump column is then formed of a series of equal sections, or units, placed end to end, the air main running alongside of them, and a numerical illustration will give a clear idea of that arrangement and of its results. It will only be mentioned at this time that all the elements of an air-lift of that type can be determined with the same degree of accuracy as the details of an elab-

orate plunger or centrifugal pump. The figures here given are purposely approximate.

We will assume that 2000 gal. of water is to be raised per minute to a vertical height of 1424 ft. Were we to pump water against 1424-ft. head the pressure per square inch at the foot of the delivery pipe would be about 640 lb.; a displacer would have to use compressed air at that pressure and even somewhat higher. The total lift of 1424 ft. will be divided into 100 equal units. Each unit consists of a tank, open at its upper end, and which may be of rectangular cross-section. A vertical eduction pipe is suspended in that tank with its open lower end a few inches above the bottom. Directly under it is the compressed-air nozzle, connected by a branch pipe to the air main. The lower unit is connected with the water supply, which maintains into it a depth of 11.1 ft. The eduction pipe passes through the bottom of the sec-

FIG. 4. LOW-PRESSURE AIR LIFT.

ond unit, and has its open upper end 11.1 ft. above that bottom; it is therefore a plain straight pipe open at both ends. The same arrangement is repeated in each unit; that is, each has a separate air jet and an eduction pipe rising to the top of the next. Each unit therefore consists of a rectangular tank, open at the top, and containing two parallel eduction pipes, one for its supply, the other for the discharge.

This being understood, the pump is ready to start, and air is turned on in the lower unit. As the head of water is 11.1 ft., a pressure of 5 lb. per square inch is sufficient. The emulsion of air and water rises up the eduction pipe and overflows into the second tank; the air, completely expanded, escapes in the shaft, while the water fills the space in the second tank not occupied by the eduction pipes. This water is picked up by air jet No. 2 and sent into the third unit, and so on, the same process being repeated through all the successive units to the top. An initial submergence of 11.1 ft. and an air pressure of 5 lb. gauge are all the requisites of the total lift: in the same locality, and with the same type of outfit, they would answer equally well for any other value of that lift.

Low Pressure Air Lift

The annexed diagram, Fig. 4, shows the general arrangement of the pump. Especial attention is called to the following points:

1. Since the units are all of equal length, this 'low-pressure' arrangement consists in splitting up the entire lift into a series of shorter ones with a theoretic submergence of 50%, the total efficiency being obviously the same as in each independent unit, regardless of their number. Whatever the total lift is, the submergence need not be more than the depth of the water in the first unit of the series.

2. The low air-pressure can readily be obtained from centrifugal blowers; this means a great reduction in first cost and maintenance of air-compressing outfit.

3. Whatever be the total lift in the same locality, at no portion of it are the air or water pipes to resist more than 5 lb. pressure to the square inch. Wood stave pipes or rectangular ducts are therefore quite acceptable, so that the pump can be built on the spot and kept in repair with local resources.

4. Each eduction pipe is cut off between two successive units, and a slip joint is used for connection. Any unit can therefore be detached from or attached to the line without disturbing the rest. These units, being identical, may be kept in readiness; any one of them may be placed at any point along the line.

5. In any specific case, the unit intended to form the pump column (and which is quite comparable to a link in a chain) is designed to perform a certain duty; that is, to raise a certain volume of water, at a certain altitude and mean temperature, and with a certain air-pressure. The volumetric ratio of free air to water is thus determined, and such a unit will

fit a 60-ft. lift or a 6000-ft. lift equally well, be it in a mine shaft or in crossing a range of mountains. A change in one of the above elements in the design of the unit influences the others to an extent that can be determined. The simplicity and cheapness of construction make alterations in shape easily practicable.

6. At starting time, all the units are empty except the lower one, and each one is connected to the air main, so that, when air is turned on, it would blow off and be wasted all along the line. It is therefore necessary to provide each unit with an air valve automatically closed and thrown open when water reaches the submergence level in that unit. These valves are all identical and interchangeable, they are of simple design, entirely automatic, and they can be removed and replaced in a moment.

7. The pump requires no foundation, being suspended by cables during the unwatering period, and each unit is supported by the shaft timbers when stationary. The details of its handling deserve and have received special attention.

8. At an assumed altitude of 4650 ft., each unit in the case at hand consumes 500 cu. ft. of free air per minute, making the capacity of the air-compressing plant 50,000 cu. ft. per minute, a figure by no means abnormal with centrifugal blowers. Here appears a unique feature of this type of pump, inasmuch as these 50,000 cu. ft. of air are discharged every minute into the shaft, where they create a powerful draft: this can readily be utilized for ventilation, either by suction up the shaft or by establishing a down draft, and this duty is performed at no additional expense. This twofold service of the air for drainage and ventilation, with the motive power placed in safety, introduces in the equipment of a mine a unique and additional element of economy. The pump will, of course, operate under water, in spite of the low air-pressure, because the first 'active' unit is always the one nearest the surface, those below it (as they might in case of sudden flooding of the shaft) are 'dead' and inoperative, so that the work of the air-compressors is always measured by the actual lift.

These remarks, it is hoped, may suffice to draw attention to a system of mine pumping which escapes most of the objections mentioned against the familiar types of station plants. It does not involve any but simple, well known, and tried principles of action, and yet, it presents some practical and economical advantages of its own. It is not claimed, nor is it true, that the low-pressure lift should in all cases supersede any other types of pump; it has been worked out, and it is specifically intended for high lifts and large volumes of water; and when unwatering and draining a deep mine, it can accomplish some work which a pump of the usual design cannot do economically. It is very much cheaper in first cost than its equivalent in capacity, and it can be repaired with local resources and labor, without resorting to a well equipped and too often distant machine-shop.

The Lake Superior Copper District in 1913

By R. H. MAURER

The copper mines of the Lake Superior copper district of Michigan during 1913 produced approximately 145,000,000 lb. fine copper, a poor showing compared with other years. The normal output of the three counties comprising the copper district is roughly 220,000,000 lb. per year. The decrease this year is directly traceable to unfavorable labor conditions generally, and in particular to the great labor strike which began July 23 and continued in force to the end of the year, though much weakened after the first two months of the conflict. The year opened with 19 producing companies operating almost at capacity, despite a perceptible shortage of labor, a condition that in recent years has become almost chronic in its persistence. It promised to equal, if not surpass, the preceding year in point of production and dividends earned and disbursed, but as the year grew older, labor became more and more scarce, with a consequent decrease in production, particularly noticeable in the outputs of the older and deeper mines. The labor war during the last six months of the year effectually stopped production at a number of important mines, and closed practically all of the newer mines, among which production is merely incidental to development work, but of respectable proportions in the aggregate.

Production

Production during the first six months of the year was just under 105,000,000 lb. copper, or at the rate of 210,000,000 lb. per year, which compares with 218,138,408 lb. copper produced in 1912; 219,840,201 lb. in 1911; 221,462,984 lb. in 1910; and 231,870,496 lb. in 1909. These figures are for copper actually mined during these periods and not smelter returns, which always include more or less copper mined in previous years, and which in 1912 is reported to have been 231,112,228 lb. fine copper. The smelter output will again be greater than the output of the mines, but the difference will be small. There is at the end of this year very little unsmelted copper mineral on hand.

The production of silver is comparatively light. Considerable silver is found associated with the copper in the mines opened on the Calumet conglomerate and Pewabic lodes, all obtained as a by-product in the process of electrolytic refining to which much of the copper is subjected, but the quantity is never sufficiently large to give the district a standing of importance among the recognized silver-producing states. The normal production of silver is about 500,000 oz. per year. As the quantity of silver produced is entirely dependent upon the amount of copper taken from these certain beds, the output this year will necessarily be small, and is not likely to exceed 200,000 ounces.

A table of productions showing the outputs of the several mines as nearly as may be calculated at this time, actual figures in many instances not being available for some months to come, is appended:

| Company. | Fine copper 6 mo. ending June 30. | Fine copper total for 1913. |
|-----------------------|--------------------------------------|--------------------------------|
| | Lb. | Lb. |
| Ahmeek | 7,893,340 | 9,100,000 |
| Allouez | 3,510,000 | 4,200,000 |
| Baltic | 7,042,000 | 8,686,000 |
| Calumet & Hecla | 29,780,000 | 53,420,000 |
| Centennial | 1,135,000 | 1,400,000 |
| Champion | 9,600,000 | 11,448,000 |
| Franklin | 1,000,000 | 1,040,000 |
| Isle Royale | 3,338,000 | 4,680,000 |
| Lake | 900,000 | 1,000,000 |
| Mass | 1,400,000 | 1,500,000 |
| Mohawk | 4,817,400 | 5,369,000 |
| Osceola | 9,070,000 | 11,686,000 |
| Quincy | 8,374,800 | 10,894,800 |
| Superior | 1,705,000 | 3,078,000 |
| Tamarack | 3,666,000 | 4,142,000 |
| Trimountain | 4,000,000 | 4,888,000 |
| Victoria | 600,000 | 1,500,000 |
| Winona | 1,350,000 | 1,550,000 |
| Wolverine | 4,033,600 | 4,488,000 |
| Totals | 103,215,100 | 144,069,800 |

The average price received for the finished metal was just under 15.5 cents per pound, giving the output of the district a gross value of approximately \$22,500,000 and making available for dividends the sum of \$8,344,788, which amount was distributed by nine companies during the twelve months. The market price of Lake copper ruled fully one cent under the average of the previous year. The average cost per pound of copper produced was approximately 13 cents for all companies, compared with 10.25 cents in 1912.

Considering the unusually small production, the dividend showing is most gratifying though it may be added that several of the companies were of necessity forced to draw on surplus accumulations of other years, and the year's disbursements therefore do not truly represent the earning abilities of the several companies during the year just closed.

The mines, or those workings that may properly be termed as such, are with few exceptions in excellent physical condition, and only two are threatened with early exhaustion, namely, the South Kearsarge mine and the Wolverine mine, the former with about four years' life remaining and the latter with an estimated life of about eight years on the Kearsarge lode. Less than one-fourth of the known mineral area of the district has been touched, practically the entire western horizon along the western sandstone remaining unexplored, and though many of the mines are now very deep and approaching the limits of workable depth, this

generation will not witness the exhaustion of these mines excepting those noted and possibly the mines on the Calumet conglomerate, which so far has been found workable only in that part which is owned by the Calumet & Hecla and Tamarack companies. This formation will probably be worked out within the next twenty years. The Osceola mines and the newer mines of the Copper Range company have an assured life of upward of forty years and the 'Old Reliable' Quincy is not expected to turn the corner inside of the next seventy years. An annual production of 200,000,000 lb. copper will probably be maintained for at least twenty years to come. The output may even exceed this figure, and a smaller average annual output is certainly not indicated.

There have been no important new discoveries of copper deposits in this district within the past ten or twelve years, excepting those in the Lake district and on the Mayflower lode, both apparently of limited extent, only partly proved, and of no considerable proportions. As the total copper production of the United States is constantly increasing through the development of other fields, a further decline in the percentage column, if not in actual production, may be expected. The district has been quite thoroughly prospected within certain well defined areas, yet only about one-quarter of the known mineral belt has been explored. The western rim, along the great sandstone contact, marking the presumed limits of the mineral area, for a distance of more than one hundred miles, remains practically untouched. What this horizon may yield or disclose under proper exploitation is problematical. Certainly no man can know positively that the production of copper in this district will cease with the exhaustion of the present mines, many of which undoubtedly will be worked out within the next generation or two, but its position as the premier copper producer, which it rightfully held so many years, is unquestionably lost forever.

The present trouble with the Lake Superior copper district is solely one of labor. Viewed from the standpoint of the mine operator, labor conditions are very unsatisfactory, principally because labor is scarce and partly because the labor strike which began in July has driven, and for more than a year previous did drive, efficient labor away in great numbers to other fields. This condition had to be met by drawing on the unskilled labor market, and unskilled and inexperienced workers are dear at any price. But this is only a temporary condition which must eventually change for the better. In the sixth month of the strike a material improvement is already noticeable. By no means all of the old employees are in sympathy with the strike and the majority have again returned to work in the mines after a short period of idleness. The position of the Western Federation of Miners is greatly weakened, and the strike which was forced by this organization against the wishes of the majority of the mine workers of this field, as has since been ascertained, appears all but ended and certainly is not so formidable as it was

only three or four months ago. The difficulties between the mine operators and this labor union, which at the beginning embraced a minimum wage scale of \$3 per day, a shorter work-day, and recognition of the union, has simmered down to recognition only. The demand for an eight hour day has been granted. An average wage of better than \$3 per day for all workers has been in existence for several years. There remains only the question of recognition of the union. This the operators are unwilling to give and will not give, and the position of the Western Federation of Miners in this district is thus made clear. The sentiment of the general public is against this organization; and the people residing in this district, forming an organization known as the Citizens' Alliance, with 40,000 members (the population of the district is about 85,000), have demanded the expulsion of the paid labor agitator with a polite request that the Western Federation also withdraw.

Late in December the union officials were seriously considering the advisability of continuing the strike and a vote of the strikers will probably be taken. The striking mine workers are beginning to see the hopelessness of their fight after about five months of useless efforts, and the rank and file may now be expected to vote for a return to work.

A brief review of the several companies in the order of their importance by counties follows:

Houghton County

The important producing mines of the Lake Superior copper district are with few exceptions within the confines of Houghton county, and this county also holds the most promising undeveloped copper deposit discovered in recent years. Its copper mines give employment to upward of 15,000 men. The Calumet & Hecla stands high among the largest copper producers of the world. It is the premier dividend payer among the metal mines of the globe, with a total disbursement of \$123,250,000 to date. The total amount of copper taken from its mines now stands in excess of 2,500,000 tons. Depth and declining copper content have had their effect, however, and this great mine will probably be entirely worked out within the next twenty years. The mines on the Osceola and Kearsarge beds can never compensate for the loss in production from the richer conglomerate lode, but may be expected to yield respectable profits over a long period of years to come, and these profits will be greatly augmented by profits derived from the treatment of the millions of tons of mill tailing wasted in earlier operations and now made available through the introduction of greatly improved milling methods.

The Copper Range group of mines is in excellent physical condition with the exception of the old Atlantic mine, which has been idle since 1906. The Baltic has grown somewhat leaner with depth and shows occasional signs of decay, but once again gives promise of increased production. The Trimountain shows continued improvement, and is gradually round-

ing into shape for heavy production. Champion also carries a noticeable betterment in the lower reaches of the mine and again in the newer openings to the southward. The active mines of this combination yielded 25,000,000 lb. copper during 1913, despite unfavorable labor conditions, and the productive capacity does not appear to have been reached.

The Quincy is an old and very deep mine. About one-quarter of the copper bed on which the mine is opened has been entirely worked out. Its holdings, however, are so extensive, and so much unmined ground remains that the life of this Company is estimated at not less than seventy years. The copper content holds steady at about 15 lb. copper per ton. Osceola will within the next few years suffer the loss of a valuable asset in the South Kearsarge mine, which is rapidly nearing exhaustion. This loss will in good measure be offset by a growing betterment noted in the workings of the North Kearsarge mine. The Osceola Branch mine is of no particular promise, but may be worked with profit for a great many years to come. The Wolverine had an exceedingly bad year. Mining operations are confined to the Kearsarge lode. Exploratory operations in the horizon of the Osceola and Old Colony lodes proved unpromising and this work has been suspended. Production also has steadily declined, and the mine will likely suffer exhaustion within the decade. The Tamarack mine is deep and unprofitable. Operations on the conglomerate lode are unsatisfactory, and the Osceola lode shows but little encouragement. The mine is in a hopeless condition, with small chances for profitable operations, except under most favorable labor conditions and a high metal market.

The Isle Royale has been a great many years in the making and has finally attained success. The first dividend disbursement by this Company was made in March, 1913. The mine is expanding wonderfully and promises to reach a productive capacity of at least 15,000,000 lb. within a few years. The Superior has succeeded in developing a valuable copper deposit in two beds in the horizon of the Baltic lode, and is making a creditable showing in copper production, but, unfortunately, without much profit for the shareholders. The Hancock seems to have opened workable copper deposits in several formations and is preparing to begin production on a commercial scale early in the new year. The Winona has all but proved to be a losing venture. Much time and effort was spent during the year in extending underground openings and in providing an efficient concentrating mill that should result in a closer saving of the exceedingly fine copper occurring in this formation. The future of this Company depends upon the successful outcome of experiments involving the use of a new concentrating process, which the Company was giving a trial late in the year.

Keweenaw County

The copper mines of Keweenaw county include a number of important producers which have a com-

bined output of 18,500,000 lb., or approximately 13% of the district's total copper output. This county was of first importance in the early days when mining was confined exclusively to the fissure veins. These were found exceedingly profitable but no deposits of this character are being worked today. About 1500 men find employment in the mines of the district.

The Ahmeek, one of the very richest copper mines of the entire district, has made material advancement in the development of its mine, and the property is now easily capable of yielding 20,000,000 lb. fine copper yearly. It has an assured future of at least 45 years. The Mohawk mine, opened on the northerly extension of the Kearsarge amygdaloid, on which the Ahmeek also is opened, is given a new lease of life by reason of the exceptionally favorable developments in the south area. Development work during the year revealed copper ground of excellent quality at a number of points. The Allouez mine is slowly developing into a producer of importance. Ore reserves have been materially increased, and an era of profitable operations is assured. The Ojibway mine, opened on the extreme north end of the Kearsarge amygdaloid, was forced to suspend operations during the year owing to lack of working capital. Development work gave rather indifferent results, and this is largely responsible for the failure of the Company to secure funds. The Keweenaw Copper Co. passed the entire year in exploratory work and in this obtained fair showings of copper at various points along the strike of the Ashbed lode. The past efforts of this Company to find copper deposits of commercial value were uniformly unsuccessful, and it is therefore gratifying to note that a turn for the better has come. The showings on the Ashbed merit development.

Ontonagon County

Ontonagon county, third and last of the triumvirate of counties comprising the Lake Superior copper district, numbers among its mines the Lake, Mass, and Victoria, ranking in importance in about the order named. There are also numerous prospects, including the White Pine, South Lake, Indiana, North Lake, Algomah, Bohemia, Onondaga, and Adventure. These enterprises give employment to about 1000 men.

The producing mines, Lake, Mass, and Victoria, yielded approximately 4,000,000 lb. fine copper, which was less than 3% of the total output of the Lake Superior district. These mines are not expected to yield in greater proportion for several years, though each can with further development easily double the present rate of production. None of them promises to develop into mines of the first magnitude, and it is by no means certain that any will reach the dividend stage within the decade. Among the prospects, White Pine and South Lake stand well to the front. Both are developing workable copper deposits, and profitable operations in the White Pine are practically assured. The lesser prospects, particularly Indiana, North Lake, and Bohemia have an even chance for success.

Thawing Frozen Ground for Placer Mining

By ARTHUR GIBSON

The term 'frozen ground' refers to ground perpetually frozen, or in other words, ground that never thaws by nature. Such 'frozen ground' is encountered in the extreme northern portion of the American continent, in Alaska, and Canada, and is also found in Siberia.

The process of artificially thawing frozen ground

considerably in the same locality and within short distances. The principal factors governing the cost of thawing are as follows: (1) amount of ice contained per cubic yard, (2) cost of fuel, (3) cost of labor, (4) amount of condensation due to long and poorly insulated pipes, (5) amount of condensation due to low temperatures during the winter, (6) method of

PLACER DRIFT MINING AT NOME. THAWING FROZEN GROUND.

can be accomplished by various methods, either by direct or indirect heating. In direct heating, burning or banked fires are built against the face to be thawed. Indirect heating is accomplished by heating a medium or secondary element, which performs the work of thawing. The secondary elements mostly used are: (1) heated rocks, (2) hot water, or (3) steam. Both experience and practice have proved steam to be the most effective and efficient medium.

The following efficiency and cost data are collected from actual placer-mining operations in the Cape Nome Mining district, Seward Peninsula, Alaska, but will apply to other localities of like nature by proper adjustment of the cost of fuel, labor, board, and local conditions. One frequently hears that it costs so many cents per cubic yard to thaw frozen ground in a certain locality. These statements, although in many instances true and derived from actual operations, are misleading, in that the cost per cubic yard may not only vary with different localities, but may even vary

mining or application, and (7) the scale upon which operations are conducted.

Heat Required to Thaw Frozen Ground

The temperature of perpetually frozen ground on Seward Peninsula, so far as known, remains nearly constant around 28° above zero Fahrenheit, or 4° below the freezing point, excepting close to the surface where the temperature is affected by the atmospheric heat or cold during the summer and winter seasons, or in the immediate proximity of subterranean water channels or thawed ground. I will assume that the frozen gravel deposit contains 2850 lb. of solids and 260 lb. of ice per cubic yard, and it is desired to heat this deposit from 28° above to 36°, or to a temperature 4° above the freezing point. How much heat is then required, expressed in B.t.u.'s, per cubic yard?

The coefficient of thermal capacity (specific heat) for solids is 0.2, that for ice is 0.5, and that for water is 1.0. The latent heat of fusion of ice is taken at 142

¹Assumed values based on excavated dirt swelling 25% over dirt in place.

²Number of men employed per day thawing ahead of the dredge is given as 3.5. This is thus explained: the night pointman also acts as oiler on the dredge during the night and his time is thereby divided into one-half for the thawing and one-half for the dredge.

Columns No. 1, 2, and 3 refer to the Linda Association claim on Center creek; No. 4, Bench 1, Center Creek; No. 5, the Tundra Association; and No. 6, the Otter creek property.

| | |
|--|-----------------|
| B.t.u. per pound. Then: | |
| 2850 lb. of solids raised 8°, from 28° to 36°, 2850 × 8 × 0.2 | B.t.u. 4,560 |
| 260 lb. ice raised 4°, from 28° to 32°, 260 × 4 × 0.5 | 520 |
| 260 lb. ice at 32° to water at 32°, 260 × 142... | 36,920 |
| 260 lb. water raised 4°, from 32° to 36°, 260 × 4 × 1.0 | 1,040 |
| Total heat required for the ice..... | 38,480 |
| Total heat required per cu. yd. of ground. | 43,040 |

This plainly illustrates the rapid increase of heat required for only a small increase of ice per cubic yard, and it shows further that under these conditions the ice requires 92.5 times as much heat as the solids. With crude oil of a fuel value of 18,000 B.t.u. per pound or 142,416 B.t.u. per gallon; or with coal of a

according to the number of men employed.

The table presented contains only the actual operating expenses, no charges for management, interest on investment, or depreciation of the outfit being considered or included. No. 1 to 5, inclusive, are the figures for underground stope-mining where the steam points are used in a horizontal position. No. 6 contains the data with regard to thawing ahead of a dredge where the steam points are used in a vertical position.

The fuel used in all of the above cases is California crude oil, averaging 17.5°B., weight 7.912 lb. per gallon, and containing 18,000 B.t.u. per pound or 142,416 B.t.u. per gallon.

The foregoing data are compiled from the common practice among some of the best miners on Seward Peninsula, Alaska, but which could no doubt be improved under scientific management. Judging from the fuel consumption, it is evident that it requires

SETTING A 20-FT. STEAM POINT.

ARRANGEMENT FOR THAWING AHEAD OF DREDGE.

fuel value of 12,000 B.t.u. per pound; and assuming the efficiency of boiler and distributing plant at 50%, there will be required in the above example to thaw one cubic yard of frozen ground:

43,040

= 4.782 lb. of crude oil, or

9000

43,040

= 0.604 gal. of crude oil, or

71,208

43,040

= 7.173 lb. of coal.

6000

The variation in the cost of fuel noted in the accompanying data is due partly to the fact that in general the prices have been raised during the last year, although some unexpired contracts maintain the former and lower prices; and partly to the different freight rates, which are proportional to the various distances between the supply station at Nome and the mines, being lower during the winter than the summer season.

The cost of labor for this particular work, firemen and pointmen, is \$3.50 and \$4, respectively, during the winter, and \$5.50 and \$6, respectively, during the summer season. Board, including fuel and cooks' wages, ranges from \$1.08 to \$1.35 per man per day,

from 80 to 100% more fuel during the winter than during the summer for underground drift-mining. Fuel for thawing ahead of a dredge appears very high. This is principally due in this case to the ground, which contains between 60 and 85% ice. Labor, duty per man per day for thawing, varies to a great extent, as it depends largely on the composition of the deposit, whether it is sand, light or coarse gravel, or ground containing large rocks which render the driving of the steam points difficult.

Miners frequently overlook some of the most vital factors relative to the most efficient and economical means of thawing, such as: ascertaining and gauging the proper distance between the steam points; the correct time of steaming; the proper time for the dirt to lie idle between thawing and excavation to evenly absorb and equalize the heat transmitted. The success of the venture depends greatly on the proper adjustment of these factors. The thawing of deep ground for dredging purposes has so far proved more or less unsuccessful, due principally to the steam condensing and losing its greatest heating value before reaching the end of the steam point. This, however, is only a matter of application and can be adjusted under a proper system.

Rhodesian Crushing Plants

The varying characteristics of Rhodesian ores in the different mining fields of Matabeleland and Mashonaland have resulted in the employment of various types of reduction and treatment plants at the different mines. With the exception of the battery of Nissen stamps running in the City Deep mill, all the reduction plants of the Witwatersrand are of practically uniform pattern, and consist of ordinary gravitation stamps and tube-mills. The stamps are of varying weights in different mills, and there are two or three sizes of tube-mills employed; otherwise the reduction plants at work from one end of the Reef to the other are of the same type and design. The Transvaal Chamber of Mines output sheet is thus a very different schedule from that issued by the Rhodesian Chamber of mines, in so far as details of crushing plant are concerned. The Rhodesian statement, apart from the numerous small 'dolly' plants in operation, shows that, in addition to stamps, the following types of crushing plant are in use: Chilean mills, Gates rolls, Huntington mills, grinding pans, pneumatic mills, Eureka crushers, and internal rollers. The list is as follows:

Matabeleland

Agincourt: 5 stamps and 1 grinding pan.
 Bushtick: 24 stamps and 3 tube-mills.
 'C': 10 stamps and 1 Chilean mill.
 Carry: 1 Huntington mill.
 Colleen Bawn: 6 stamps and 1 grinding pan.
 Lonely Reef: 20 stamps and 3 tube-mills.
 Nelly: 2 Huntington mills.
 Old Nic: 15 stamps and 4 grinding pans.
 Winifred: 1 internal roller.
 Cinderella: 1 Eureka crusher.
 Collingwood: ball-mill.
 Gaika: 5 stamps and 1 Chilean mill.
 Globe & Phoenix: 40 stamps and 10 grinding pans.
 Gothic: 15 stamps and 2 grinding pans.
 Red Hill: 1 Chilean mill.
 Selukwe Columbia: 1 Chilean mill and 3 grinding pans.
 Wanderer: 4 Gates rolls.

Mashonaland

Battlefields: 2 Chilean mills.
 Brilliant: 7 stamps and 1 grinding pan.
 Concession: 5 stamps, 1 Chilean mill, and 2 grinding pans.
 Dowry: 1 pneumatic mill.
 Dreadnought: 1 Chilean mill.
 Giant: 30 stamps and 2 tube-mills.
 Pickstone: 10 stamps and 1 Chilean mill.
 Shepherds: 5 stamps and 1 tube-mill.
 Thistle-Etna: 1 Chilean mill.
 Eldorado Banket: 20 stamps, 2 Chilean mills, and 8 grinding pans.
 Kimberley Mashonaland: 6 stamps and 2 tube-mills.
 Louise Grand: 1 Huntington mill.

It will be evident from the above that there is considerable scope existing in Rhodesia for the various makes of crushing appliances, other than gravitation stamps. Any new type of crushing or fine-grinding machinery, provided it does effective and economical work, appears to be assured of a fair trial; and success, once established, is likely to induce other properties to take the device up.—*South African Mining Journal*.

Detection of the Platinum Metals in Cupellation Beads

*It has long been known that the presence of small amounts of platinum in cupellation beads causes a surface crystallization visible to the naked eye, and according to experiments by C. O. Bannister and G. Patchin, the following conclusions are arrived at: (1) In the silver-gold beads the crystallization of silver and of gold is distinctly traced in the structure. The visual appearance of beads composed of equal amounts of gold and silver is shown to be similar to that of beads containing over 1.6% of platinum. (2) It is shown to be possible by a simple microscopic examination to detect platinum in cupellation beads when present below 1.6%; that is to say, when present below the amount necessary to cause crystallization visible to the naked eye. (3) The presence of iridium in small quantities may be detected in silver beads by the strained appearance of the crystals caused by internal stresses. (4) The presence of traces of rhodium may be detected by a crystallization of the beads in which the facets of the crystals are distinctly visible. When over 0.03% of rhodium is present, this is indicated by a bluish gray color and a large amount of spitting. (5) Ruthenium is indicated in cupellation beads by a black crystalline deposit firmly attached to the bottom edge of the beads, and in the experiments carried out was always associated with a herringbone-like structure when examined by the microscope. (6) Palladium causes a structure similar to that found in the presence of platinum, but yields satisfactory evidence of its presence by the coloration of the parting acid. (7) No specific indications are afforded, by the tests carried out, of the presence of osmium. (8) The indications obtained of the presence of iridium are found to apply equally well to osmiridium.

Milling plants on the Comstock lode in 1875, according to the *Virginia Chronicle* of December 1913, contained the following equipment:

| | | | |
|----------------|-----|-------------------------|------|
| Mills | 41 | Agitators | 20 |
| Stamps | 890 | Clean-up pans | 29 |
| Pans | 352 | Capacity of mills, tons | |
| Settlers | 156 | per day | 1400 |

Several of these mills were treating tailing only.

*Abstract from *Bulletin* No. 111 of the Institution of Mining and Metallurgy.

Evolution of Suction-Gas Power in Western Australia

By J. C. AULDJO

The first suction-gas plant at Kalgoorlie was installed on the Great Boulder mine in 1907 for firing roasting furnaces. The experiment proved a failure, as it was found that there was not sufficient heat in gas generated from charcoal when it came to forced work, and the management reverted to the wood-fired furnaces to get the required output from them. In 1908 a suction-gas plant was installed on the Great Boulder No. 1 Co.'s St. George mine at Mt. Magnet, but proved a source of annoyance for a time until it was understood. About the same time Messrs. Moss Bros. installed a small plant at their treatment works at Kalgoorlie. In 1909 two suction-gas engines of 50 hp. each were installed in Kanowna to drive custom stamp-mills, and, in the same year, six suction-gas engines varying from 30 up to 80 hp. were installed in small treatment plants around Kalgoorlie. Although giving general satisfaction and requiring little attention, even from laymen, there was a constant liability to intermittent trouble from the sudden over-heating of the cylinder, which no one could explain. At this time Mr. Truman, a custom mill operator, installed an 80-hp. engine on the Mt. Ferrum mine, and discovered that the cause of the trouble was the opening of the air valve too wide, and excessive heat resulting from an excess of hydrogen in the burning gas. Mr. Truman generously made his discovery known, and, since then, no complaints regarding suction-gas plants have been heard, as it was proved that any excess of heat could be immediately checked by regulating the air-valve. Since then the number of these engines has largely increased, and is still increasing. At all the outside centres, such as Ora Banda, Leonora, Mt. Morgans, Black Range, Meekatharra, and Bullfinch, suction-gas power has quite superseded steam for operating treatment plants. In spite of the economy which can be effected by their adoption, gas engines are unlikely to supersede steam on the large mines at Kalgoorlie, as large electric plants have been installed. The great advantage of suction-gas plants is that they require little attention and practically no technical knowledge. So far as Western Australia is concerned all the plants were operated by charcoal-gas generators well into 1912, when the Cambridge generator, previously tried in New Zealand, was introduced. This generator has a down instead of an up draft, and can be fired with wood, shavings, or sawdust, in addition to coal, lignite, coke, or charcoal. In January, 1913, Messrs. Jordan and Degenhart, two engineers on the staff of Bewick, Moreing & Co., devised the Commonwealth generator, also a wood consumer. By tests with a 200-hp. Crossley generator, using charcoal costing \$14.16 per ton against a Commonwealth generator using wood costing \$3.84 per ton, they found that the cost of power could

be reduced from 30 to 20 cents per ton of ore treated, the reduction being 7.5c. in fuel and 2.5c. in up-keep. The proportion of charcoal consumed to wood being 100 to 172. The test was made with a 200-hp. Crossley engine, single cylinder, 24-in. diameter by 32-in. stroke and working at 166 revolutions per minute. This drove a 20-stamp-mill of 1250-lb. stamps, Krupp tube-mill and vacuum-filter, treating 185 tons of ore per day. The comparative cost of fuel per brake horse-power hour tested at Kalgoorlie is as follows: steam, with wood costing \$3.12 per ton, 0.70c.; suction gas, with charcoal costing \$14.16 per ton, 0.64c.; and Commonwealth gas generator, with wood costing \$3.12 per ton, 0.30 cents. There are now three down-draught wood-gas generators on the market, the Cambridge, Commonwealth, and Akroyd, for all of which points of superiority are claimed. The Commonwealth is easily getting ahead of its rivals, and is being installed on

A 250-HP. COMMONWEALTH GENERATOR USING WOOD IN 6-FT. LENGTHS. THIS SUPPLIES GAS FOR A 220-HP. TANDEM GAS ENGINE DEVELOPING 183 I.H.P. CONSTANT, AT THE QUEEN OF THE HILLS MINE, MEEKATHARRA, WESTERN AUSTRALIA.

many of the mines, managed by the firm of Bewick Moreing & Co. Three of these generators of 380 hp. each, and consuming 6-ft. lengths of wood, are shortly to be installed on the Sons of Gwalia mine at Leonora, to operate a 660-hp. 4-cylinder Kynock gas engine, and two Crossley engines of 400 and 167-hp., respectively. Similar generators of 200-hp. have been installed on the Yuanmi and Queen of the Hills mines. Except on the larger mines these suction-gas plants are in charge of laymen with other duties to attend to, as no engineer's certificate is required, no technical knowledge appears to be essential, and firing has only to be done twice a shift.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Tin Mining in Tasmania

The Editor:

Sir—The successful exploitation of very low-grade mines always calls forth the admiration of mining men in parts of the globe where, on account of expensive transport and inefficient labor, the working of such mines is an impossibility. Therefore, everyone engaged in tin mining in this country will have read with interest the account of the Anchor mine in Tasmania, in the *Mining and Scientific Press* of October 18, 1913. At this property ore containing as low as 2.38 lb. of tin per ton is treated by stamp-milling and concentrating.

Any tin miner in Bolivia, and probably in other parts of the world, excepting Australia, would consider himself to have attained perfection in tin dressing, if he could succeed in making an average mill tailing of 2.3, or even 3 lb. of tin per ton. Assays of tailing at the leading mines of Cornwall are given as 3 to 6 lb. metallic tin per ton for sand, and 7 to 9.5 lb. for slime, according to *The Mining Magazine* of April and June 1913. In Bolivia, where the minimum tin content of ore milled is 2 to 3%, and might average 8%, losses are much higher, even in modern and well equipped plants. As an example, I will mention that the lowest tailing assays, which I have ever obtained from a fine grained 6% ore was 0.32% for the sand, and 0.65% for the slime, corresponding to 7.2 and 14.6 lb. metallic tin per long ton, respectively. Tailing assays from other mills here are difficult to obtain because the tailing is not automatically sampled.

It is to be regretted that no particulars are given about the methods of concentrating the low-grade material at the Anchor mine. From the published data I tried to figure the extraction of tin in the milling process, but found a strange discrepancy. This was that the tin in the concentrate amounted to 302,003.07 lb., which had been recovered from 104,732 tons of ore containing 2.38 lb. per ton. According to this, the quantity of metallic tin in the millheads was only 249,262.6 lb., from which 302,003 lb. was obtained, if the concentrate is calculated in long tons, and 269,645.6 lb., if the short ton is used. These figures call for extractions of 120 and 108%, respectively. However perfect the method of dressing may be at the Anchor mine, it is obvious that these results are impossible, and some mistake must have been made in the data, probably in the tin content of the ore. On such low-grade material an extraction of 50% would be very good work, as is proved by the results of the Cornwall Tailings Co., England, which, in spite of all

efforts, cannot raise its extraction above 40%. This Company is treating material of 19 lb. metallic tin per ton, seven times richer than the ore at the Anchor mine is supposed to be. On the other hand, Tasmanian tin ores have a reputation of being very pure, and it might be possible to get a better recovery than in Cornwall, although the ore is so much poorer. I hope it will not hurt the feelings of the engineer in charge of this Tasmanian tin mine if an extraction of 50% is assumed. A tin content of 5.76 or 5.15 lb. per ton is arrived at, depending whether the long or short ton has been used for the weight of the concentrate. These figures look more reasonable, and agree better with results from another Tasmanian mine, namely, that of the Mount Bischoff Tin Mining Co., which recovers about 7 lb. metallic tin per ton of ore.

It is easy to prove that ore with 2.38 lb. tin per ton could not be profitably treated with a working cost of \$0.84. If the average price of tin during 1912 averaged £205, the value of one ton of concentrate of 71.6% was £146 15s., less smelting charges of about £6, according to *The Mining Magazine* of March 1912. This leaves a value of about £140 15s., equal to \$680 per ton of concentrate, or \$0.425 per pound of tin. Therefore an extraction of 1.97 lb. tin per ton would be required to pay expenses, corresponding with an extraction of over 82% on 2.38-lb. ore. Such an extraction is impossible with a ratio of concentrating of nearly 700 to 1, and rock of this grade does not deserve the name of ore. Anyhow, it is remarkable enough, that material of 5 to 6 lb. tin per ton can be worked at a profit, and I am certain that it would be greatly appreciated by the tin mining community, here and elsewhere, if Tasmanian engineers would give a detailed description in the technical press of the mining and treatment methods of an ore which would be considered waste in most other countries.

M. G. F. SÖHNLEIN.

Machacamarca, *via* Oruro, Bolivia, November 23.

[The last report of the Anchor Tin Mining Co. showed a loss of \$8500 on the year's operations, showing that Mr. Söhnlein is correct as to the property being worked at a loss, yet not nearly so much as his figures would indicate. The Anchor tin mine is known as being the lowest grade in the world, and everything is in its favor for cheap work. Mt. Bischoff costs total \$1.15 per ton, using similar methods of treatment. It might interest Mr. Söhnlein to know that in New South Wales, dredges are handling gravel containing 1 lb. and under of tin per cubic yard, at a profit. Of course dredging is considerably cheaper than open-cut mining and stamp-milling, yet these results are obtained. Tasmania produces 3700 long tons of black tin, 65% metallic, per annum, and this comes from low-grade mines where the tin ore is either treated by hydraulicking, or simple mining and milling methods. Most of the black tin produced in Tasmania is treated by the Mt. Bischoff smelter at Launceston, and metallic tin is exported.—EDITOR.]

Special Correspondence

BUTTE, MONTANA

REVIEW OF THE MINERAL INDUSTRY, 1913.

No new mines of importance were opened in Montana coalfields during the year. The three principal producing fields are Red Lodge in Carbon county, Roundup in Musselshell county, and the Belt field in Cascade county, supplying respectively the Northern Pacific, the Milwaukee, and the Great Northern railway systems. Statistics issued by the state coal mine inspector estimate the 1913 production at 3,365,000 tons. Except for railway use the increase of production from Montana coalfields was not important. Wyoming on the south, and Alberta on the north furnish better coal for retail consumption, while the coke industry in Montana is dead. The clean hard coke now used at Montana smelters comes from Colorado and Canada. The strike of the coal miners in the Trinidad fields of Colorado is having an indirect effect on the Montana coal trade. Much of the coal used in southwestern Montana comes from the Wyoming fields, but the coal scarcity in Colorado has made a better market there for the Wyoming coal, so that Montana customers have been neglected. This has undoubtedly increased the sales of Montana coal at home. In western Montana, some attempt has been made to mine and market the Miocene lignites. Their poor storage qualities, high ash, and low heating power restrict their use to limited markets near the mine. The immediate future of the coal industry in Montana looks none too bright. Beside the better coal which comes in from neighboring states, it now appears that the railways and other power consumers are to use hydro-electric power in place of coal. The Anaconda Copper Mining Co. has taken the initiative and displaced nearly all its steam plants with electricity from water-power. In like manner electric locomotives have displaced steam traction almost entirely on the Butte, Anaconda & Pacific railway. Now comes the Chicago, Milwaukee & St. Paul railway with plans matured and equipment in part ordered for the electrification of 450 miles of its main line from Harlowton, Montana, to Avery, Idaho. No definite announcements have been made so far by the other transcontinental roads; but the prediction can be safely made that they will all be electrified within the next few years. Not that water-power can supply them all, but gas engines in power-plants at the coal mines will displace the present wasteful system of separate power units with each train load.

There was no production of oil and gas in Montana in 1913, but mention is made of it here because of the several serious attempts which have been made during the year to find commercial fields. Across the state from north to south, east of the Rocky Mountains, more or less drilling has been done, but so far without success. The zinc-mining industry in Montana is particularly interested in the possible development of natural gas. The heaviest burdens which the zinc mines of this state have to bear are the freight rates to, and treatment charges of, the zinc smelters in the Mississippi Valley.

The one operating cement plant in Montana, at Trident, on the Mississippi river, has had a successful year, and is said to have been operated nearly to capacity, which is 1500 bbl. per day. South of Livingston, near Gardner, another cement plant is in course of erection.

No phosphate rock is mined in Montana as yet, but the U. S. Geological Survey has done a lot of prospecting for it, and has reserved a number of areas where it has been found. The smelters have so far taken no active steps toward the use of sulphuric acid in the manufacture of fertilizer.

The sapphire mines at Yogo, in Fergus county, are reported to have had a prosperous year.

The important gold-producing counties are Madison, Silverbow, Broadwater, Fergus, Blain, and Lewis and Clark. The source of the gold varies widely. In Madison county the four dredges of the Conrey Mining Co. are the chief producers. In Silverbow county the gold is a by-product of the copper ore, and does not amount to much. It takes 5,000,000 tons of ore to yield 30,000 oz. of gold, which means about 12c. per ton. The milling ores are found in Fergus and Blain counties, both of which contain several cyanide plants. Many other counties of the state yield various amounts of gold, but are not comparable in importance with those above mentioned.

Silverbow county so far excels all other counties of the state in silver production that the others need hardly be mentioned. It should produce close to 11,000,000 oz. again, while the rest of the state may total 1,500,000 oz. The silver from Butte, in Silverbow county, is chiefly a by-product of the copper ore, averaging about two ounces per ton of ore mined. Jefferson and Granite counties are the others which each produce several hundred thousand ounces of silver. The ore is mostly shipped to smelters for treatment, and is not milled

MAP OF WESTERN MONTANA.

in local plants. Beaverhead county will show an increased silver production for 1913, because of the reopening of the Hecla district.

Copper production is of course the most valuable mineral industry of Montana. The other copper districts of the state are hardly worth mentioning. Their sponsors keep heralding them as 'second Buttes,' but there are only three other counties that will pass the 100,000 lb. mark for the year. These are Beaverhead, Broadwater, and Granite counties.

The Coeur d'Alene produces more lead in a day than Montana does in a month. Montana has no important lead mines. The lead which Montana produced in 1913, came from ores mined chiefly for their precious metal content. Many counties in the state ship some lead ore, but most of it comes from Jefferson, Silverbow, Beaverhead, Cascade, and Lewis and Clark counties. If electric smelting of complex sulphides proves practicable, there are many idle mines in Montana which will be able to ship a lead product.

Zinc mining is becoming an important industry at Butte. For 1913, Montana will be credited with about 85,000,000 lb. of zinc, nearly all from the Butte & Superior mine at Butte. For Butte, the zinc outlook is bright, and it is probable that other mines will become zinc producers within the next few years. In other districts the zinc mines have not shown much progress. The zinc generally occurs with other sulphides

which prevent satisfactory wet concentration. If the hydro or electro-metallurgists bring forth something practical the situation will be changed, but under present conditions there is no promise of important zinc production in any other part of Montana but Butte.

Tungsten has been found in several localities in Montana, but apparently not under commercial conditions as yet, for no production is reported for 1913. There has been some talk of the molybdenum in Emigrant cañon, Park county, but no shipments have been made, to my knowledge.

No railroads have been built in Montana during the past year primarily to open up mining country, but some have been built which benefit mineral districts. The Chicago, Milwaukee & St. Paul has built branches in Fergus county, improving transportation conditions to several mining districts. Both the Milwaukee and the Great Northern have been building through parts of eastern Montana, which may contain commercial coalfields and possibly oil and gas. A railroad used principally for ore transportation is the first in Montana to adopt electric locomotives. The Butte, Anaconda & Pacific railway is now using electric haulage on both its passenger and freight trains. The electric power comes from Great Falls, 130 miles distant.

The mining industry is considerably interested in hydro-electric developments in Montana. Power is made cheaper, cleaner, more dependable, and less expensive to install; and for the hydro-electric processes it is indispensable. Most of the developed water-power in the state is on the Missouri river and its headwaters in various places. In addition, however, the Clarke fork of the Columbia at Thompson Falls is being harnessed, and power from that source will soon be available. At present the hydro-electric plants in Montana can furnish 72,000 horse-power.

No unexpected developments of importance were made in the Butte mines in 1913. No new mines of importance have come to the front. The disseminated copper of the Butte & Duluth mine has been proved by drilling to be more extensive than was anticipated. The Butte & Superior Copper Co. has its zinc mine on a better producing basis. The Anaconda company has begun prospecting for zinc in the old Nettle mine west of Big Butte, and will sink a deep shaft there. The Rainbow Lode Development Co. is prospecting for zinc east of the Butte & Superior; its shaft is nearly 1000 ft. deep now.

The Southern Cross mine in the Georgetown district has been shipping steadily to the Anaconda smelter. Its present rate of production is 250 tons per day. The Barnes-King Mining & Development Co. has had the most successful year of its existence. It bought the North Moccasin mine in Fergus county and paid for it out of profits from the mine. The Company is also prospecting the Pegan-Gloster mine at Marysville. The mines in the Little Rockies, in Blaine county, were not particularly active in 1913. The Ruby Gulch Co. was running until the mill burned down last fall. The Keating mine and the Ohio mine in the Radersburg district were producing during the year, but no new developments of importance were made in Radersburg.

PLATTEVILLE, WISCONSIN

REVIEW OF THE WISCONSIN ZINC INDUSTRY, 1913.

In all respects save one, 1913 was the greatest year that the Wisconsin zinc-lead fields ever experienced. There was as much exploration of ore ranges in the centre of active mining operations and virgin ground as during the boom period of 1906. While there were only a few new power, mining, and concentrating plants built during the year, it was one of the best years considered from the viewpoint of building operations. The high prices for metal which started with the year were reflected in exceedingly good prices for ore, and mining companies all over the field, acting on the presumption that another such year as 1912 would be enjoyed in the field, ex-

erted extra efforts to secure a maximum production. A steady decline in prices for spelter set in about the middle of February, which continued throughout the remainder of the year, and the cheerful conditions prevailing soon after the first of the year gave way to discouragement, a curtailed production, in some quarters reduction of working forces, and in others a complete shut-down indefinitely. From the standpoint of profits, the past year gave little to the producer compared with 1912. One thing especially noteworthy, and to the great credit of the operators, is the fact that wages were maintained all the year in spite of declining markets. Another feature, equally noticeable, proved conducive to the fine production reported, was in the competition between ore buyers, particularly the lower grades, in which the Mineral Point Zinc Co. almost eclipsed the other smelters. The increased offerings enabled many low-grade producers to keep operating who otherwise might have been compelled to suspend operations altogether.

The principal producers in the field during the year were the New Jersey Zinc Co.; the Wisconsin Zinc Co., a subsidiary organization of the American Zinc, Lead & Smelting Co., under

NATIONAL ZINC CO.'S SEPARATING PLANT.

the personal management of Homer S. Snow; the Vinegar Hill Zinc Co.; the Cleveland Mining Co.; and the Frontier Mining Co. A conservative estimate of purchases made in the field by the New Jersey Zinc Co. was about \$1,000,000. The Wisconsin Zinc Co. purchased the East End and Federal mines, and 500 acres of mining lands in the New Diggings district. The Vinegar Hill Zinc Co. operated seven mines scattered over the field, in addition to a large ore-separating plant at Cuba. The Frontier Mining Co. developed and equipped six mines, built an electrostatic separating plant of the Huff type at Linden, and made a large output of ore. Milwaukee capitalists were active in five of the fifteen mining camps of the field. The Cleveland Mining Co. installed two new modern mining equipments, besides performing considerable useful prospect work, and developing two new zinc ore producers.

Reviewing the field by districts the following more important events transpired: The New Jersey Zinc Co. purchased the Highland, Franklin, and Minter mines at Highland, at a cost of \$250,000. All were more or less equipped. The central power-plant of the Kennedy mine was enlarged and remodeled at great cost, two new mines were developed, and a pump shaft with complete equipment at a cost of \$10,000. The O. P. David mine at Montfort, the only producer in this district, developed new orebodies and completed a new shaft, also pumps and a Lawson aerial tram. The Linden district boasted six active producing mines, the Ross Bros., Glanville, Optimos No. 1 and 2; Hinkle, and Saxe-Pollard. Big finds of zinc ore were made in all except the Hinkle. Mineral Point showed little mining activity. The Mineral Point Public Service Co. increased its capacity to furnish electric power for the northern half of the field. Heavy consignments of carbonate of zinc ores were delivered to the New Jersey Zinc Co., from Colorado. New

Mexico, and Arizona. The Miffin district reported shipments of zinc ore from three stations, Harker, Rewey, and Livingston. From Livingston came the ores of the Coker mine, owned by the New Jersey Zinc Co. Also the ores from the Rundell & Ellsworth mines, the property of the Vinegar Hill Zinc Co. The Peni Mining Co., of Milwaukee, shipped from Rewey and Harker. The Grunow, Peacock, B. M. & B. and Lucky Six mines, active all year, delivered ore to Harker. The Biddick mine, a new property, was developed and equipped. Heavy purchases were made in this district by the New Jersey Zinc Co. The Slack mine passed out of existence and the equipment offered for sale. Platteville saw a very large decline in output, due to a long list of unexpected events. The great Empire mine, for eight years a steady producer, paid \$250,000 in dividends, and was worked out. Also the Homestead was exhausted. The Klar-Piquette mine, the heaviest dividend payer of this field, closed down the last week in December on account of prices. The only active producer during the year was the East End mine. The Empire roasters ran double shift on ores from the Wisconsin Zinc Co.'s mines. These two gave to Platteville the showing it made for the year. Cuba City witnessed much prospecting and the amalgamation of the Midway, Board of Trade, Jarrett, and Little Dick mines into one parent organization to be known as the Little Dick Mining Co. The Wicklow was abandoned. At Elmo near at hand the Vinegar Hill developed the Masbruch mine. A double complement of 18-in. cross-head lift pumps, the heaviest in the field, were installed here. The Benton district took the lead over all its competitors for the year with a production of over 46,000,000 lb. of zinc ore. Six new mines were developed, equipped, and placed in operation, the Martin, Bull Moose, San Souci, Hird, North Blende & Ewing. The Frontier Fox, Crawhall, Indian Mound, Ewing, and Lawyer & Temple mines gave to this district its splendid output. About 20 low-grade producers with equipment were put out of commission during the year. New Diggings furnished the sensations of the year. Here, two new ore ranges were proved by drills, exceeding in extent anything ever before discovered in this field. The first was found on the Thompson land adjoining the Crawhall mine on the east. An east and west deposit was determined to be over 1100 ft. long, from 40 to 65 ft. thick, and about 200 ft. wide. Shullsburg experienced an 'off' year. Hazel Green prospered through the operations of the Kennedy and Cleveland mines, both of which averaged four cars of ore per week, all delivered to Mineral Point. Two new mines were developed by the Cleveland Mining Co., the Lawrence and Scrabble Creek. Both were supplied with independent plants operated by electricity. The Witherbee estate was purchased and will be mined from the Cleveland side. Four-ton electric motors are being used here for tramping ore to mill.

The production of ores for the year 1913, for the Wisconsin zinc-lead field, by districts, is shown below:

| Camp. | Zinc, lb. | Lead, lb. | Sulphur, lb. |
|---------------------|-------------|-----------|--------------|
| Benton | 46,010,000 | 1,048,600 | 39,331,650 |
| Hazel Green | 31,276,000 | 776,900 | 82,000 |
| Platteville | 30,132,000 | 560,170 | 4,130,500 |
| Galena | 26,458,000 | 1,004,390 | 2,385,500 |
| Livingston | 24,722,000 | 140,000 | |
| Linden | 20,476,000 | 606,830 | 3,274,880 |
| Cuba | 18,571,000 | 1,029,680 | 6,924,690 |
| Shullsburg | 18,396,000 | 949,820 | |
| Harker | 6,836,000 | 119,270 | |
| Highland | 2,886,000 | 100,000 | |
| Montfort | 2,648,000 | 161,610 | |
| Mineral Point | 2,365,000 | 59,200 | |
| Rewey | 1,382,000 | | |
| Dodgeville | 608,000 | 70,000 | |
| Potosi | 308,000 | 40,000 | |
| Total | 233,074,000 | 6,666,510 | 56,127,220 |

The above figures show actual deliveries from producing mines, but included in same is the refined ore from separating plants. The Mineral Point Zinc Co. shipped during the year to the smelters 430 cars of roasted zinc ore, equal to 31,520,000 lb. Among smelter representatives, the output was divided as follows: Mineral Point Zinc Co., 51,521 tons; Grasselli Chemical Co., 21,459 tons; National Separating Co., 11,313 tons; Illinois Zinc Co., 8495 tons; Empire Roasters, 8360 tons; M. & H. Zinc Co., 6636 tons; Linden Zinc Co., 2799 tons; Joplin Separator Works, 2824 tons; American Zinc Co., 2550 tons; Wisconsin Separating Co., 550 tons; Sandoval Zinc Co., 30 tons; total, 116,537 tons. There was left in storage at various places in the field between 4000 and 5000 tons of concentrate.

H. S. Snow, general manager for the Wisconsin Zinc Co., when interviewed on the prospects for the current year, said: "I am optimistic and think things will be better. I don't look for anything big, but for a fair market." With conditions fairly normal, Wisconsin should be able to produce not less than 150,000 tons of zinc ore during the present year. No appreciable gain in the production of lead ore need be anticipated. Sulphur production will be less than that shown for the year just past.

JOHANNESBURG, TRANSVAAL

NATIVE LABOR.—WHITE MINERS AND STRIKES.—GOLD OUTPUT.

The outlook for the Rand gold-mining industry is not very bright. The darkest cloud is the chronic scarcity of native labor; in fact, it may be stated that there is less available for the mines today than has been the case for many years. During the winter months, May to September, there is always a shrinkage, but this year the scarcity of natives was much accentuated by the ill advised strike in July. This drove many of the more intelligent natives home to their *kraals* at the first available opportunity. The result was that, in July and August alone, the labor supply was depleted to the extent of 20,000 natives at the gold mines alone. Fortunately, the shrinkage of natives has decreased month by month, until by the beginning of the year it is anticipated that a slight gain may be shown in the returns. Up to July 1913 the output of gold on the Rand was showing the usual steady increase, the May figures creating a highly creditable record; but the strike and the attendant riots so upset the industry that the growth of the first six months has been converted into a loss. The total gold output for the year will for the first time in the history of the Rand record a decline. Several thousand Europeans have been dispensed with from the mines, work is almost impossible to obtain, and the closing down of several deep and low-grade mines has not tended to improve matters. The strike brought no material advantages to the men, simply because they had no substantial grievances, but it has created a bad feeling between themselves and their employers, and a condition of affairs not altogether pleasant to contemplate. The agitators and socialists have made the best of their opportunity to create ill feeling between the men and their employers.

On December 11 Sir Lionel Phillips, one of the leading managers of the Eckstein group, was shot in the street while proceeding from the Corner House to the Rand Club for lunch. He was highly respected by everyone, and this dastardly attempt on his life has given rise to the expression of much indignation. Fortunately the shots did not prove fatal, and the victim is progressing favorably.

The Chamber of Mines reports a serious decline in the gold output for November when compared with October. The decrease for the whole of the Transvaal was no less than 44,945 oz., of which the Rand alone is responsible for 43,195 oz. The shorter month is to some extent responsible for this, but usually the output materially improves during the last two months of the year. This year the continued shrink-

age of native labor has made such an improvement impossible. The total Transvaal output for November was 673,486 oz., valued at £2,860,788, of which 644,320 oz., worth £2,736,897, came from the Witwatersrand. It was confidently expected that the November output would at least reach a total of £3,000,000, and it is clear that the total gold output for 1913 will fall short of that recorded for the preceding year. The Rand, however, still possesses some recuperative power in reserve, and with an amelioration in the native labor position, progressive outputs will again become the order of the day.

NEW YORK

BRADEN MINE.—FIRST NATIONAL COPPER.—CHEAP SHARES.

Braden showed some improvement in output during December, presumably as a result of the 'all-star' staff now in charge of technical operations, Pope Yeatman and Walter Broadbridge having been on the ground for some time. It is somewhat difficult to judge the state of affairs at Braden by output figures, since the production during July was little more than one-half that in June, and the October output was double that for September. During December, the new mill at the Braden treated 93,600 tons of 2.15% ore, but only made a 70% recovery of the copper. The old mill treated 10,359 tons of 1.99% ore, with an average recovery of 80%. It is evident that the new mill is being used to keep up the output while the old one is being readjusted to obtain better results. When both mills are tuned up, and if the mine can furnish enough ore, which is perhaps open to doubt at present, the monthly output of the Braden should show a big increase.

New York is much interested in the reports from the First National, at Coram, and while it is, of course, premature to suppose that all problems have been overcome because the results during the first two days seem good, they are at least decidedly encouraging. Before getting excited over First National, it is well to remember that the California mine and the holding company are two different things. The mine is owned by the Balaklala Consolidated Copper Co., capitalized at \$10,000,000, and was reported to have about 2,000,000 tons of 2.6% copper ore and large reserves of lower-grade material, so it has a future as a producer if it can operate at a profit. The jubilation over solving the sulphur difficulty ought not to obscure the fact that the ore contains almost as much zinc as it does copper, and nothing has been said as to what effect this is likely to have on the processes for recovering the copper. If, by any chance, the zinc could be recovered as well as the copper, the mine ought to be very profitable. However, the \$10,000,000 stock of the Balaklala company is held by the First National Copper Co. with a capital of \$3,000,000. The shares of this concern are \$5 par, \$3.75 having been paid on them, and were boosted up as high as \$8 at one time by Lawson's well known methods. Recently they were up to nearly \$4, but declined to \$3 as a result of market operations. First National has been traded in a good deal on the Curb, but is not one of the favorites of the outside market, where Tonopah Merger, Canadian G. & S., Big Four, West End, Braden, Giroux, and various Cobalt companies lead in the number of sales recorded.

Speaking of the Curb, it is interesting to note that the so-called assets of J. Thomas Reinhardt were sold at auction last week at an average rate of little better than two shares for a cent. What they were like is indicated by the fact that no purchaser appeared for large blocks of Porcupine Northern, Central, and Southern, while North Carolina state bonds of a face value of \$108,000 sold for \$165.

And in talking of making the best of a bad thing, it is evident that the Assets Realization Co. is having heavy going. This is a company which makes a business of resuscitating moribund organizations, and not long ago it took

over the Heinze ventures in addition to a long list of others. Now it seems to be in need of assistance itself, for shareholders are being solicited to subscribe to an issue of \$1,000,000 in 6% notes. This organization holds about 450,000 shares of Stewart, and that stock has been declining, perhaps in the fear that it will be found necessary to put this on the market.

LONDON

AFFAIRS OF THE GREAT COBAR COPPER COMPANY.

The directors of the Great Cobar Copper Co. have had an anxious time during the past year, and their worries culminated this week when the election of two of their number was challenged by the 'insurgents and dissentients.' The result of the poll was a near thing, and the vote of censure was only defeated by a narrow margin. As readers of the *Mining and Scientific Press* are aware, the Company owns the Cobar copper mine, situated inland in New South Wales. For many years the zone of secondary enrichment yielded immense profits to the Australian owners. These men, being sagacious in their day, knew that orebodies do not persist in depth forever. If they were not fully aware of the principle of the impoverishment of the mineral deposit in depth, they knew that profitableness did not extend downward indefinitely. As they were interested in Cobar commercially rather than geologically, they wisely decided to realize future expectations in ready cash, and complacently received the suggestions of their friends to find buyers in London. After one or two futile attempts, the deal was effected in 1906 on an unusually grand scale even for London. The vendors received £800,000 in cash and £206,000 in shares. Large sums of money were raised for the reorganization of the development scheme, and for the building of a modern metallurgical plant. The share capital amounts to £932,710 and there are £667,300 debentures. The engineers on whose reports the Company was formed were C. M. Rolker, J. D. Kendall, and W. J. Barnett. Strangely enough, their estimates as regards copper content have not been verified in practice, for the recovery is nearer 2% than the 3.5% mentioned. Moreover the gold and silver have not provided as useful an addition to revenue as was expected. The Company also purchased the Chesney copper mine, and coal properties near Lithgow. The Cobar ore was highly basic and considerable silicious flux had to be purchased. Subsequently an amalgamation was effected with the Cobar gold mine which contains silicious gold ore with a small amount of copper. The two ores made an efficient smelting mixture. There were many mistakes in connection with the smelter. To begin with, the American firm that secured the contract through its English representative, repudiated the terms on which the contract was based, and the work of estimating and distributing orders for the plant had to be done a second time. Then when the plant was ready all sorts of mishaps occurred, and the directors made a scapegoat of the manager. They exhibited perspicacity when they invited H. C. Bellinger to come from Montana to straighten out the smelter. He did so well that they appointed him general manager. This venture, however, did not bring prosperity, and they and others are now blaming Mr. Bellinger, when they should probably more justly be blaming the contrariness of the ore deposit. He has resigned and the management has been placed in the hands of Bewick, Moreing & Co., whose Australian representative, G. C. Klug, is to be in charge. As far as can be ascertained, Mr. Klug is not to be continuously resident, and is only to make periodical visits, still retaining control of the many interests of his firm. People in London think this a peculiar arrangement, and argue that if Mr. Bellinger could not attend to administration, mining, and metallurgy, when the whole of his time was devoted to the Company's work, how can Mr. Klug be effective when only putting in one-sixth of his time. The explanation surely must

be that separate sub-managers are to be appointed for the mine and the smelter, as has already been done in connection with the concentrator, where G. A. Laird has recently been put in control. This reminds me that the concentration plant erected at the Chesney mine gave trouble owing to no qualified man being on the spot. The Chesney ore is silicious and not high in copper and gold. Consequently it has to be concentrated. The ore is amenable in jigs, but the losses on tables are serious, so that the Minerals Separation flotation process has been adopted. The jig department has not been at all satisfactory, but on the other hand, the flotation plant, by recovering 77% of the metallic content of the tailing and of the reground jig-middling, has done extremely well. No doubt Mr. Laird will soon put things on a more satisfactory footing. The worst feature of the position at Cobar, however, is the present condition of the orebodies. The northern orebody, which was lost below No. 10 level, has not yet been found, though the workings are now down to No. 14 level. The central orebody shows a diminution in area, and a creep in the southern and central orebodies has rendered 150,000 tons unavailable for stoping, at any rate for the present. It is convenient here to give some figures relating to present output and reserve, the figures being for the year ended June 30, last. During this time 222,377 tons of Great Cobar ore was smelted, together with 45,779 tons from the Cobar gold mine, 8738 tons of concentrate from Chesney, and some purchased ore, making a total of 288,172 tons. This yielded 5811 tons of copper, 27,136 oz. gold, and 127,543 oz. silver. The average copper content recovered equaled 2.017% of the ore treated. According to Mr. Bellinger, the ore reserve was 1,468,749 tons averaging 2.5% copper. At the Cobar gold mine, the reserve is estimated at 308,545 tons averaging 1.7% copper and 6.8 dwt. gold. At the Chesney, the orebody is narrowing with depth and the ore reserve is estimated at 612,986 tons averaging 2.58% copper. The accounts for the year show a working profit of £81,925, and £34,355 was brought in from the previous year. Out of the balance, £40,009 went to debenture interest, and £57,500 to the purchase of debentures, while £48,414 was written off the account for reorganizing the metallurgical department, an expense incurred a few years ago. The seriousness of the situation may be gauged by the fact that W. Pellew-Harvey, a director who joined the board on the absorption of the Cobar gold mine, felt it his duty to take action and to visit the mine, at the same time studying similar practice to be found elsewhere in Australia. His report has been issued by the directors, and it will be found that in many cases he is unable to agree with Mr. Bellinger's estimates. Mr. Pellew-Harvey is known in the west of America, and he is eminently a reliable man. Another inspection was made during the past year, this time by C. S. Herzlg who went on behalf of a London group financially interested in the Company. His report was much more optimistic. Because his more hopeful prognostications have not been fulfilled, this group commenced the agitation to which I referred at the beginning of this letter. A meeting of dissentients was called a month ago, when Rowland Feilding, a mining engineer, and F. Kimber Bull, a lawyer, made an attack on the present board of directors. When the regular yearly meeting of shareholders was held last week, the re-election of the chairman, Andrew Haes, and of W. J. Barnett, a director, was opposed, and the names of Messrs. Feilding and Bull were put forward as alternatives. The polling showed that a large amount of genuine dissatisfaction exists among shareholders, for the old hands were re-elected by a not very substantial majority.

The Cobar mine was expected to produce 10,000 tons of copper per year, double the amount that has been possible. The profits were expected to be sufficient to redeem £100,000 debentures every year and provide also handsome dividends to the shareholders. The debenture holders have received their interest, but an insignificant amount of the debentures has been redeemed. The present position is far from satisfactory.

BRITISH COLUMBIA

THE BRITANNIA MINE AND OPERATIONS. — THE INDIAN RIVER DISTRICT.

During the past year, the Britannia Mining & Smelting Co., that owns the Britannia mine, on Howe sound, acquired nearly all of the mineral claims adjacent to and along the strike of the mineralized zone, thereby securing a solid block of ground nearly five miles east and west by about a mile wide north and south. The amount of mineralization in the area has always been recognized as of great extent, and the Company has proved by working openings in one portion of the property, known as the Fairview zone, that the mineralization extends to a depth of over 2000 ft. below the summit of the ridge, that it has a length of upward of 1200 ft. along the strike of the zone, and a minimum width of approximately 500 feet. The Britannia mine is on the coast range, which is built up principally of granitoid rocks, mostly coarse quartz diorites or grano-diorites, and the mineralized zone of this property occurs in an inclusion consisting largely of slate alternating with a dark intrusive, probably a diorite-porphry, usually crushed and altered into a greenish chloritic schist. In treating the low-grade ore, concentration is used, and the most successful process so far attempted has been by the Minerals Separation flotation process. The concentration is in the ratio of about 4 to 1. The production from this property during 1913 was 212,000 tons of ore containing about 1.5% copper, 40c. in gold, and from 0.5 to 1 oz. silver per ton. The equipment is to be enlarged shortly by the installation of a new concentrating mill with a daily capacity of 2000 tons. The system of transportation of the ores from the mine to the beach is being improved by the construction of a double-track gravity tramway, one mile long, with an average grade of 15%; also a 'switchback' track, five miles long, with a 3% grade, on which gasoline locomotives will be used; a 9 by 12-ft. tunnel 3600 ft. long, and a 1200-ft. vertical chute connecting the tunnel with the upper mine workings.

The Indian river rises in the mountains about 8 miles to the southeast of the head of Howe sound, and flows south, emptying into the north arm of Burrard inlet, some distance east from the city of Vancouver. The headwaters of this river are situated about 6 miles east from the main workings of the Britannia mine. Although trails have been covered by Indians and trappers in this country for many years past, it is only within the last three years that any mineral discoveries have been reported in the neighborhood of the headwaters of the Indian river. The prospectors who made these discoveries for a long time considered that the mineralized zone was an extension of the Britannia country, but an examination which was made last summer showed that the general geology is practically the same in both localities, yet the wide zone of schists in which the Britannia orebodies occur is lacking on this portion of the Indian river, so far as at present known. Outcrops of chalcopryrite are, however, found in a zone some 500 ft. wide, with a northwest and southeast strike, and so far as at present known having a length of about 10,000 ft. and appearing to be rather paralleling the Britannia zone than as an extension. Because of the heavy growth of underbrush, prospecting has been difficult. Although about 12 mineral claims, each 1500 ft. long by 1500 ft. wide, have so far been located along this zone, yet it is impossible until more work has been done to connect up the various outcrops along the line of strike. It would appear, however, as though there were a large number of lenticular deposits of copper ore in a quartzose gangue rather than a well defined continuous lead. Some of the outcrops have a width of from 10 to 25 ft., as proved by stripping and open-cut work, but in no case could be found sufficient work done to establish the length of any one outcrop beyond 100 feet.

General Mining News

ALASKA

It is estimated that 35 dredges were operated in Alaska in 1913, and that these produced gold to the value of about \$2,650,000, as against \$2,200,000 in 1912. There were also 6 or 8 dredges which, for one reason or another, were not operated in 1913. A number of others are under construction or planned for, according to Alfred H. Brooks of the U. S. Geological Survey.

Eight copper mines were operated on a productive basis in 1913. It is estimated that about 42,000 tons of ore yielded 19,700,000 lb. of copper valued at \$3,014,000, \$160,000 of gold, and \$150,000 of silver. The decrease of over 9,000,000 lb. in copper production compared with the previous year is due to the fact that the largest producer was practically closed down for about four months.

The Katalla oilfield continues to be the only place of any importance in the petroleum industry in Alaska. Another well was drilled in 1913 to a depth of about 800 ft. This, and some of the old wells, by pumping furnished petroleum for a small refinery. The gasoline, which is of high grade, finds a ready market at the settlements on Prince William sound and Cook inlet.

About 15 placer mines were operated in the Kenai peninsula during 1913, but work was hampered by low-water conditions. Most of these were only very small operations, but one relatively large hydraulic plant was at work on Resurrection creek, and two smaller ones on Bear creek. Prospecting dredging ground on Kenai river was continued. The hydraulic plant on Crow creek, north of Turnagain arm, was operated throughout the open season.

CORDOVA

(Special Correspondence.)—The last payment, on the total of \$146,000, on the option of the Smith-Monahan properties on Valdez creek, has been paid by the Valdez Creek Placer Mines Co. One mile of 36-in. pipe was ordered from the Joshua Hendy Iron Works of San Francisco, and this has been shipped to the property. By July 1, 1914, it should be complete. The daily capacity will be about 4000 cu. yd. of gravel.

Cordova, December 25.

FAIRBANKS

About 150 placer mines were operated in the Fairbanks district for a whole or a part of 1913. These gave employment to about 1000 men in winter and 3000 in summer. Preliminary estimates indicate that the value of the placer gold production was about \$3,450,000.

IDITAROD-INNOKO

As in the other Yukon camps, the shortage of water greatly hampered mining operations. This condition, together with the fact that certain claims were not worked because they were being combined into large holdings for the purpose of exploiting in a large way, led to a great curtailment of gold output compared with the previous year. Preliminary estimates indicate that the value of the gold production from the Iditarod-Innoko districts was about \$2,000,000, of which about \$200,000 is to be credited to the latter area. There was some prospecting of lode claims, but the cost of mining is so great that few have been attracted to quartz development, according to Alfred H. Brooks of the U. S. Geological Survey. In the Iditarod region the largest production came from the mines on Otter and Flat creeks, but mining was also done on Happy, Willow, Moore, and Chicken creeks and in Glen gulch. The dredge on Flat creek was operated throughout the summer, and plans have been made to install a boat

on Otter creek. The chief activity in the Innoko district in 1913 was on Little creek, where a considerable area of rich new placer ground was discovered. Work was continued on Spruce and Ganes creeks. Ophir creek is worked out and practically abandoned. Yankee creek ground has been acquired by a dredging company, and mining is at a standstill pending the construction of a dredge.

NOME

Trade at Nome during the season of 1913 was as follows: Vessels arrived, 43, of 79,143 tons register; general merchandise from United States, 15,534 tons; fuel oil, 6719 tons; coal, 13,841 tons; lumber, 1,386,937 board feet; placer tin exported, 100 tons; and gold, 135,313 oz. Passenger arrivals were 1795, and departures 2943.

Thirty-one dredges were operated for a part or the whole of the summer, on the Seward Peninsula, according to Alfred H. Brooks of the U. S. Geological Survey, with an estimated gold recovery of a value of \$1,800,000. These dredges had

COUNCIL, ALASKA.

a combined daily capacity of 33,300 cu. yd. Four new dredges were erected in 1913, and several others were in course of construction. Others are contemplated. In addition to 31 operated, there were 6 dredges idle in 1913. Of the dredges engaged in productive mining, 11 were in the Nome, 11 in the Solomon, 5 in the Council, 1 in the Kougarak, and 4 in the Fairhaven, and 1 in Port Clarence district. Of other than dredge mining there was very little.

RUBY

According to H. M. Eakin, placer mining in the Ruby district, as a whole, has shown considerable advancement over the previous year in spite of certain unfavorable circumstances. The distribution of profitable placers has proved more irregular than was expected, so that after working out limited areas many plants have had to take up prospecting for new deposits rich enough to be worked instead of continuing actual mining. The season of 1913 was exceptionally dry, so that only the plants equipped with pumping apparatus could work at full capacity. All told, there were 41 plants engaged in actual mining in the Ruby district, operating 38 claims on 14 different creeks and employing a total of about 230 men. There were also a number of prospecting outfits working on these and neighboring creeks. Of the 41 plants, 33 are equipped with steam machinery, aggregating over 750 hp. The other 8 plants use manual methods.

ARIZONA

COCHISE COUNTY

A fire occurred on the 200-ft. level of the Czar mine on December 31, but the helmet crew put it out after 24 hours' fighting. Surveyors are working on the site in the Warren district chosen by the Copper Queen company for its new concentrating plant. This will treat the low-grade ores proved on Sacramento hill.

GILA COUNTY

(Telegraphic Correspondence.)—The Inspiration flotation plant has started work, and high recoveries are being made. Miami, January 13.

(Special Correspondence.)—During December the Miami mill treated 102,000 tons of ore yielding 3,300 lb. of copper.

Development of the Captain orebody is being actively carried on. The 420-ft. or main tramming level is 75% completed, and work on the sub-levels is under way. An electric pump of 2000 gal. per minute capacity has been installed on the McLean ranch, near Burch, where the Company recently sunk a 24-in. well, 120 ft. deep. It is capable of furnishing a large amount of water, and is to be used as a reserve, in addition to the Old Dominion supply.

The Inspiration 600-ton flotation test-mill is in operation. It will probably be worked three shifts per day with 25 men. Rudolph Gahl will be metallurgist; C. E. Singer, of Los Angeles, chemist; G. E. Hunt will be in direct charge of the mill, and J. G. Flynn and C. G. Dressel will act as shift bosses under him. J. L. Greninger will represent the Minerals Separation Co. locally. Construction work at the concentrating plant is proceeding satisfactorily. The ore-storage bins and sampling mill will soon be ready for the corrugated-iron covering. Another part of the incline conveyor housing between the bins and coarse-crushing plant was completed during the week. The American Bridge Co. has this work in hand. Concrete is being poured for the air-compressor foundations at the main east and west shafts. About 50 carpenters and helpers have been laid off, as the form work here is finished. Concrete for the retaining walls at the concentrator site is still in progress, but is nearly completed. In December there was 4200 ft. of development covered in the Inspiration mine. Further raises are being driven under the Joe Bush ore dump.

Work at the Old Dominion mine in 1913 showed good results generally, especially on the lower levels. It is intended to install two 1200-gal. electric pumps at 1800 ft. when the 'A' shaft is completed to that point. Skips replaced cages in September last, and the new crushing and sampling system was brought into use. Two 100,000-cu. ft. per minute fans were started at the Kingdon and 'C' shafts respectively. The United Globe end of the mine showed satisfactory results. A large quantity of machinery was erected at the 'A' shaft and mill. The copper output in 1913 was about 30,000,000 pounds.

Globe, January 9.

GREENLEE COUNTY

On New Year's day the old smelter of the Arizona Copper Co. was shut down for good. It has been in operation for about 35 years. The new plant is on the San Francisco river below South Clifton. To a depth of 5 ft. around the old plant, the ground is being excavated for treatment.

PINAL COUNTY

The annual report of the Iron Cap Copper Co. states that development in 1913 covered 1610 feet. At 650 ft. the slope is 485 ft., and at 800 ft. it is 47 ft. long. Ore shipments totaled 4899 tons yielding 763,822 lb. of copper. The year's profit was \$38,460.

YAVAPAI COUNTY

The Crosby mine is down 300 ft., \$4 ore has been opened, and at 200 ft. another shoot has been recently cut. There is a 10-stamp mill and cyanide plant on the property.

CALIFORNIA

AMADOR COUNTY

The Kennedy Company is being sued by Lingi Tonelli for \$10,000 damages, for personal injuries sustained in the mine early in December. The case will be heard in San Francisco.

The contract for building the Plymouth mill is to be awarded before the end of the month by Burch, Caetani & Hershey at San Francisco.

The first of the four tailing wheels built by the Kennedy M. & M. Co. was tested last Saturday and found to work satisfactorily by the officers of the Company. Argument in the Kennedy Extension-Argonaut case was concluded the same day.

ELDORADO COUNTY

Freight rates on ores between San Francisco, Sacramento, and points on the Placerville branch of the Southern Pacific railway have been reduced as follows:

| Value of ore per ton. | Present rate. | New rate. |
|-----------------------|---------------|-----------|
| \$50 to \$75 | \$2.75 | |
| \$60 | | \$2.10 |
| \$70 | | 2.25 |
| \$80 | | 2.40 |
| \$100 | | 2.50 |

NEVADA COUNTY

The annual meeting of the Le Duc Mining Co. was recently held in San Francisco. B. A. Penhall is general manager and vice-president. The long raise to the surface at the mine is finished, and several veins were cut. At the Golden Center mine, Grass Valley, the water is being removed by an air-lift pump, after which an electric pump will be lowered. The Idaho-Maryland mine has been shut down temporarily. Local miners have leased the Rose Hill at Grass Valley.

PLUMAS COUNTY

Gravel mining in the southern part of the county is likely to see a revival. A bond and lease has been taken on the Claybanks mine by W. H. Loftus of Los Angeles. The property is said to be an extension of the drift from the Feather Fork mine.

SIERRA COUNTY

At the Tightner the new shaft is down over 100 ft., the vein being followed. It is 7 ft. wide at this point. The stamp-mill is working full time.

SISKIYOU COUNTY

A silver-copper property is being developed on Rail creek by the Isabella Copper Mining Co., composed of Oakland people. The vein is an extension of that in the Dewey mine, near Gazelle. The McKeen mine, near Callahan, has been bonded to J. S. Bagg and associates.

SHASTA COUNTY

The Field process plant at Redding is now being tested.

TUOLUMNE COUNTY

The Springfield Tunnel & Development Co., at Sonora, has driven its new 8 by 8-ft. drainage tunnel 100 ft. It is at sufficient depth to drain the gravel deposit. The Company's capital has been increased from \$200,000 to \$500,000. Marysville men are developing claims near the App mine.

The Providence mine has opened rich ore on the 300 and 500-ft. levels, and the stamp-mill is working. J. F. Bluett is superintendent. Work has been started at the New Albany. The Draper is being unwatered. The owners of the Golden Dawn are sanguine as to its prospects. Twenty men are employed at the Garfield. Eastern capitalists are arranging to open the Seminole and Mayflower claims. The Black Oak shaft is being deepened 200 ft. below the 1700-ft. point. Shaft sinking will also be done at the Starr King. In the Syndicate mine driving is in progress on the 200-ft. level.

COLORADO

LAKE COUNTY (LEADVILLE)

The ore and metal output of Leadville during 1913 was as follows, according to *The Herald Democrat*:

| | |
|----------------------------|---------|
| Ores: | |
| Lead carbonate, tons | 16,984 |
| Iron, tons | 83,275 |
| Sulphide, tons | 121,676 |
| Zinc sulphide, tons | 52,689 |
| Zinc carbonate, tons | 157,286 |
| Silicious, tons | 21,450 |
| Total | 453,360 |

Metals:

| | |
|-----------------|------------|
| Gold, ounces | 49,261 |
| Silver, ounces | 3,315,270 |
| Lead, pounds | 23,498,390 |
| Copper, pounds | 2,059,911 |
| Spelter, pounds | 84,751,468 |

The total value was \$9,040,359, against \$11,182,616 in 1912. Leadville's total mineral output to date is valued at \$406,451,061. In the same journal, James M. Knight reviews the year's work and present situation of the Leadville district. He considers that the current year will be one of progress. The unwatering of the 'down town' properties will be started at an early date. From Carbonate hill the greatest tonnage of ores was mined, the Western Mining Co. being the principal producer. Carbonate of zinc came from the Wolfstone, and lead ore from the Henriette claims. The Company's daily output was 400 tons of ore from 700 ft. depth, and 200 men were employed. From the Star Consolidated Mines Co.'s lessees about 350 to 400 tons of carbonate of zinc, argentiferous iron and lead ores were produced daily. About 100 men are employed. The Castle View produces 75 tons of ore, while the Yankee Doodle and Little Giant were actively operated. At Iron Hill, the Iron-Silver Mining Co. shipped large quantities of iron, lead, copper, and zinc ores, employing about 250 men. A number of lessees are working. The Louisville has been equipped

of work was done. At Birdseye the Cosmopolitan adit was driven 900 ft., cutting promising stringers of gold ore. The usual quantity of work was done at the mines on Fryer hill, Canterbury hill, Yankee hill, Rock hill, California gulch, Ball mountain, Empire gulch, Iowa gulch, and other parts of the district. The Philadelphia Leasing & Development Co. has opened 20,000 tons of ore on Yankee hill. The Yak tunnel was advanced into the Diamond and Vega ground near the head of Big Evans gulch. An interior shaft was sunk 110 ft. from near the heading, and at 100 ft. drifts driven to the ore-bodies. Thirty leases are being worked, and the tunnel is in good order. Half Moon and Lackawanna gulches received great attention during the year, on account of the good showing in the Mt. Champion mines. In the Dick Turpin claim the ore is found near a fault in the granite formation. The trend is north and south with a southeast dip. The shoot is 350 ft. long. Rich gold and copper ore is found on the hanging wall of the lode, while low-grade ore is mined next to it. The average value is \$12 per ton. The mill is treating 100 tons daily. All equipment is driven by electricity. The main adit of the Lackawanna Belle Mining Co. is in 500 ft., equal to 350 ft. depth. Three raises are in ore 6 ft. wide averaging \$20 per ton. Great results are expected from this district in 1914.

TELLER COUNTY (CRIPPLE CREEK)

The gold production of Cripple Creek during 1913 was valued at \$14,435,520, against \$14,006,741 in 1912, making a grand total of \$324,786,741, according to *The Cripple Creek Times*. At the local mills, at Colorado City, and the smelters, a total of 966,906 tons of ore was treated. The treatment of low-grade ore at the local plants is of interest as shown by the following table:

| Plant. | Tons. | Average value. | Gross value. |
|--|---------|----------------|--------------|
| Portland, Battle mountain..... | 179,918 | \$2.97 | \$ 532,866 |
| Stratton's Independence, Battle mountain | 131,026 | 2.67 | 349,887 |
| Colburn-Ajax, Battle mountain.. | 54,994 | 3.27 | 179,905 |
| Gaylord-Dante, Bull hill | 17,700 | 2.95 | 52,315 |
| Wild Horse, Bull hill | 13,865 | 3.38 | 46,910 |
| Kavanagh-Jo Dandy, Raven hill. | 19,315 | 2.10 | 40,600 |
| Isabella mines, Bull hill | 9,290 | 2.13 | 20,760 |
| Rex M. & M. Co., Ironclad hill... | 2,700 | 1.68 | 4,400 |
| Total | 428,808 | \$2.86 | \$1,227,643 |

The men engaged in treating this class of ore are: Thomas B. Crowe of the Portland, Arthur H. Finn of the Wild Horse, Philip H. Argall of Stratton's Independence, E. H. Colburn, Jr. of the Ajax, Thomas Kavanaugh of Rex-Jo Dandy mills, Edwin Gaylord of the Gaylord mill, and J. B. Neville of the Free Coinage mill.

Dividends during 1913 were as follows:

| | |
|--|--------------|
| Golden Cycle Mining Co. | \$ 405,000 |
| Cresson Con. G. M. & M. Co., estimated..... | 300,000 |
| Portland Gold Mining Co. | 300,000 |
| Elkton Consolidated Mining & Milling Co..... | 200,000 |
| Vindicator Consolidated Gold Mining Co..... | 180,000 |
| Stratton's Independence, Ltd., estimated | 120,000 |
| Strong Gold Mining Co., estimated | 150,000 |
| Mary McKinney Mining Co. | 104,740 |
| El Paso Con. Gold Mining Co..... | 61,280 |
| Stratton's C. C. M. & D. Co. | 60,000 |
| Gold King Mining Co. | 10,000 |
| Total | \$ 1,891,020 |
| Profits of leasing companies and lessees, estimated. | 350,000 |
| Grand total | \$ 2,241,020 |
| Dividends prior to 1913 | 38,128,584 |
| Total to 1914 | \$42,260,624 |

MAP OF COLORADO

with a new hoist, and 75 tons of iron sulphide was shipped daily. Ore worth \$50 per ton has been opened in the Belgian. About 150 tons of zinc sulphides per day was extracted from the Colonel Sellers. The A. Y. & Minnie shipped zinc carbonates part of the time, but only iron ore has been hoisted. At Adelaide Park the old Adelaide property has been worked right along by the owners and lessees. The Fairplay produced about 20,000 tons of ore. A cyanide plant is to be erected to treat low-grade ore. Breece hill is the centre of the gold-bearing area. The Ihex is the largest gold producer in Lake county. Six shafts are worked under lease, and 50,000 tons of gold, silver, lead, copper, and zinc ores were mined. Very rich shoots are occasionally cut. Proposed development by the Dividend Mining Co. at the Big Four claims is important. The main shaft is to be sunk to 1000 feet. Fair tonnages of ore have been extracted from the St. Louis, Garbutt, Fanny Rawlings, Bobby Burns, Penn Leasing Co., and others. Twenty-two sets of lessees are working in the Monarch Mining Co.'s claims at South Evans. At the Walker claim the Mosquito Range Co. let a contract to drive an adit until ore was cut, about 400 feet. At Big Evans gulch a considerable amount

On January 20 the Portland company will pay 2c. per share, equal to \$60,000. The Vindicator Consolidated will pay 3c. per share on January 25, equal to \$45,000.

OURAY COUNTY

Mineral production of the county in 1913 was valued at \$1,558,825, made up by crude ore and concentrates, \$1,088,950; bullion, \$459,875; and coal, \$10,000. Thirty-two properties contributed to the output. The local smelter received 4000 tons of mine and mill products.

SAN JUAN COUNTY

The San Juan region of Dolores, La Plata, Ouray, San Juan, and San Miguel counties produced in 1913 \$4,116,000 in gold, 2,847,000 oz. of silver, 21,165,000 lb. of lead, 3,630,000 lb. of copper, and approximately 8,000,000 lb. of zinc, compared with \$4,115,345 in gold, 2,562,096 oz. of silver, 20,752,156 lb. of lead, 3,000,173 lb. of copper, and 6,375,073 lb. of zinc in 1912. There was an increase for gold of \$7000 in Dolores, \$163,000 in La Plata, \$115,000 in San Juan; and a decrease of \$61,000 in Ouray and of \$224,000 in San Miguel county. There was an increase for silver of 105,000 oz. in Dolores, 200,000 in San Juan, and 71,000 in La Plata, while there was a decrease of 93,000 oz. in San Miguel county. Dolores county (Rico) made a large increase in the yield of copper, lead, and zinc, but the production of lead fell off heavily in San Miguel and Ouray counties. The yield of gold bullion in Boulder county decreased one-half and there was also a decrease of 2000 oz. of gold in ores smelted, but the silver output increased 100,000 oz. and the lead 470,000 pounds.

The American Smelting & Refining Co. reports the following yield from San Juan county ores smelted at its works: Gold, \$413,069; silver, \$493,796; lead, 7,556,391 lb.; and copper, 1,022,988 pounds.

The Frisco Tunnel Co., at Animas Forks, is starting a 100-ton mill. Emil Hensen is manager.

IDAHO

Figures prepared by the State mine inspector, Robert N. Bell, show the following output of Idaho in 1913:

| | |
|---|--------------|
| Lead, pounds | 325,000,000 |
| Zinc, pounds | 30,100,000 |
| Copper, pounds | 8,887,000 |
| Gold, ounces | 65,000 |
| Silver, ounces | 10,107,000 |
| Value for state | \$24,360,000 |
| Value for Shoshone county (Coeur d'Alene) | 21,924,000 |

An average of 40 cars of ore or concentrate per day is shipped from the latter district.

SHOSHONE COUNTY

On the 1000-ft. level of the Success mine, a shoot of good zinc ore has been opened. At 860 ft. a shoot has been driven on for 265 ft., being still in ore. The mill is being improved by the addition of a magnetic separator, a 3 by 30-ft. drying tube for concentrate, and a process for reducing metal losses in slime. H. F. Samuels controls this property, and C. C. Samuels is in charge of the mill. At the Paragon, near Murray, the shaft is being sunk to nearly 300 ft. depth. From the upper workings of the mine, lead and zinc ores are shipped. The Amazon-Manhattan adit, to connect with the Interstate-Callahan, is in 1400 ft. The Marsh mine, at Burke, is producing 150 tons of silver-lead ore per day. Development on No. 5 level is highly encouraging. On January 3 the Bunker Hill & Sullivan paid dividend No. 196, amounting to \$81,750.

MICHIGAN

HOUGHTON COUNTY

(Special Correspondence.) Every time a United States Government official comes to Houghton, the labor agitators ascribe his visit to the probability of the Government taking control of the mines, and giving them to the strikers. In

this way the ignorant miners are deluded. Men are returning to work every day, and new men are coming in to the district. The Copper Range is adding 8 to 12 men daily, and the Quincy is importing Germans, quite desirable citizens. The Calumet & Hecla continues normal operations, so does the Superior, and the Osceola is approaching that point. At the Keweenaw mines, progress is not as rapid. But the attitude of all of the men is antagonistic to the Western Federation of Miners.

Houghton, January 8.

NEVADA

LANDER COUNTY

The Kimberly United Mines Co.'s property, near Hilltop, has been examined by A. L. Moore of San Francisco. He states that the area is well mineralized, and recommends extending the Joker adit, also erecting a 20-ton mill for testing purposes. The main vein runs through three claims, and has been opened in the Joker adit for 97 feet. The Gold Star adit is in 250 ft., and a large tonnage of \$15 to \$20 gold ore has been opened. The Oro shaft, 70 ft. deep, is in a good shoot of ore.

LYON COUNTY

The two new converters at the Mason Valley company's smelter started work on January 3. They have a capacity of 4,000,000 lb. of copper per month, and will save the expense of shipping matte. At the Empire-Nevada, the Miami company has completed one drill-hole and has moved the rig to another position. Smelter returns for the first six days of December 1913 show that Nevada-Douglas shipped 759 dry tons of ore with an average copper content of 8.09 per cent.

NYE COUNTY

The Carrava Mining & Milling Leasing Syndicate is to erect three six-roller Chilean type of mills at its property at Carrava. High-grade gold-bearing ore has been shipped, and there is a large tonnage of milling ore on dumps and in the leases.

Tonopah mines produced 10,538 tons of ore worth \$257,150 during the week ended January 10. A large shoot of \$12 ore has been opened on the 500-ft. level of the West End mine. The Montañ mill is making a recovery of 92.6%, and the bullion output is increasing each month. The Halifax vein has been opened in trachyte at 1100 ft., about 280 ft. south-east of the Halifax shaft. Dividend No. 18, of 25c. per share, has been paid by the Belmont company. During the quarter ended November 30, revenue amounted to \$924,523, and net profit was \$531,716. The surplus was \$1,430,969.

STOREY COUNTY

Two Byron-Jackson pumps in the joint incline of the Crown Point and Belcher have lowered the water below the 1500-ft. level. The station is in good order, but the level has caved in places.

WHITE PINE COUNTY

Two more Star churn-drills, of 1400-ft. capacity each, have been ordered by the Consolidated Copper Mines Company. The Company has purchased 50 dump cars from the Nevada Consolidated for handling the overburden to be moved from the first steam-shovel pit at Riepetown. The Giroux company has three drills working on the Ora claim.

NEW MEXICO

LUNA COUNTY

Rich gold and silver ore has been opened in the Bi-Metallic Mining & Milling Co.'s mine near Deming in the Sierra Blanca range.

OREGON

JOSEPHINE COUNTY

The Afterthought mine on Thompson creek has been sold to Michigan and Illinois men for \$12,000. A good deal of ore has been opened by adits, and assays give high returns in gold.

SOUTH DAKOTA

POTTER COUNTY

Drilling at Gettysburg has passed through several inches of oil sand, also a seam of coal 15 ft. thick.

UTAH

PIUTE COUNTY

Nine miles southwest of Marysville is a large deposit of pink rock which contains 11% of potash salts and 37% of aluminum oxide. The Florence Mining & Milling Co., which owns a large part of the deposit, is about to erect a plant costing \$50,000 for preparing the material for market. Development has proved several million tons of mineral according to J. F. Gibbs in *The Salt Lake Tribune*.

SUMMIT COUNTY

A contract has been awarded to J. A. McIlwee for the completion of the Snake Creek tunnel near Park City. This heading is in 6700 ft., 1200 ft. below the surface and in limestone. The total length of the tunnel will be 14,350 feet. About 4000 gal. of water is flowing from the workings.

TOOELE COUNTY

Sixty miles south of Wendover, on the Western Pacific railway, in the Willow Springs district, high-grade copper and lead ore has been opened by the Western Pacific Copper Company. This ore was cut near the bottom of a 250-ft. incline shaft.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—Diamond-drilling will be done at the San Diego group of claims, on the Kitsault river, about six miles from the head of Alice arm. A good deal of work has already been done on the property, and a considerable tonnage of ore averaging 3.2% copper, and \$2 in gold and silver, has been proved. A horse trail has been made from the head of the arm. S. J. Eubank and D. F. Jones control these claims.

Prince Rupert, January 3.

The electric power-plant, smelter, and other equipment of the Granby company at Anyox is complete, and should be in proper running order by February 1.

Equipment worth about \$30,000 was purchased recently in Spokane, Washington, for the Silver Hoard mine, near Ainsworth. This will be installed in the spring. The machinery includes a 3400-ft. Riblett aerial tramway. A hydro-electric plant is to be installed for light and power purposes in the mine, consisting of a Westinghouse generator and Cassel water-wheel. The hoist will be electrically driven. An Ingersoll air-compressor has been delivered. High-grade silver-lead ore has been opened at 200 ft., and ore reserves total 100,000 tons. So far 1394 tons of good ore has been shipped. W. S. Hawley is general manager.

ONTARIO

During the period ended December 2 the Hollinger mill treated 13,140 tons of ore averaging \$15.17 per ton. The recovery was 96.16% at a cost of \$1.40 per ton for treatment. The profit was \$118,090. Porcupine mines in 1913 are estimated to have produced gold worth \$4,330,000.

During 1913 La Rose Consolidated made a profit of \$951,000. During December the Nipissing high and low-grade mills treated 161 and 6268 tons of ore, respectively, and the refinery produced 674,984 oz. silver. Hydraulic prospecting was stopped on December 8. A 2-in. vein was cut in the Keewatin country assaying 500 oz. per ton. Important developments took place in the R. L. 400 lot. The draining of Cobalt lake has been started.

CHILE

During December the Braden mine produced 2,122,000 lb of copper, the largest output in the company's history. The

old mill treated 10,359 tons of ore averaging 1.99%, and the new mill treated 93,612 tons averaging 2.15% copper, with 80.88% and 69.78% recoveries, respectively.

COLOMBIA

The Pato dredge recovered gold worth \$13,400 from 18,000 cu. yd. of gravel during the week ended December 23. Clayey water interfered with washing during the period. Results of operations have given rise to a good deal of correspondence in certain financial papers in London.

The Oroville Dredging Co., Ltd., has purchased the San Francisco gravel property, of 400 acres, which adjoins the Pato property on the Nichi river. The price paid is reported to be \$51,000. The results of five drill-holes on California hill, Pato concession, gave an average of 12c. per cubic yard.

MEXICO

JALISCO

The treatment plant for the Cinco Minas Co., in the Hostotipaquillo district, is now in operation. Louis Baird, an English mining man, who was captured by bandits at the Espada camp during the second week in December, has been released on payment of \$500. The ransom asked was \$3000.

HIDALGO

(Special Correspondence.)—The new San Francisco shaft at the Santa Gertrudis is lined with steel through its whole depth. It was sunk 30 ft. south of the old San Francisco shaft. A fine head-frame has been erected over the new shaft and is connected with the mill bins by a belt-conveyor. The San Guillermo shaft has been giving trouble for some time past.

Pachuca, December 4.

MEXICO

(Special Correspondence.)—The Rincon mine has been operated during the year, shipping 100 tons of high-grade ore per month to the smelter until recently. Twenty stamps are working, producing bullion and concentrate. Power has been short, and another 1000-hp. power-plant is being erected below the one at Pedregal. This will supply power for the rest of the mill, and electric pumps on No. 6 level of the mine. These have been 'drowned' for a year. Shaft-sinking has been stopped on account of water, but as work has been done below the shaft bottom, raising will be adopted to deepen the shaft. The Real de Arriba Mining Co. is employing a number of men.

Temascaltepec, December 4.

SONORA

Mineral exports from Sonora through the port of Agua Prieta show a slight decline in value and tonnage during December. A total of 344 cars was shipped, equal to 13,630 tons. Twelve properties were on the shipping list. El Tigre company shipped 77 bars of silver-gold bullion weighing 12,518 lb. The estimated value of exports in Mexican currency were: copper, \$1,676,800; silver, \$434,000; gold, \$197,500; total, \$2,308,300.

The Cananea Consolidated mines, mill, and smelter are operating at about 66% capacity. James S. Douglas, general manager, estimated that 24,000 tons of ore would be milled and 35,000 tons smelted in December. Development underground amounts to 5000 ft. per month. The mill at El Plano mine, 90 miles southwest of Sassabe, is to be restarted at an early date. Two companies are working in the Boludo portion of the Altar placer district. In the Magdalena district, La Mina de Plata stamp-mill is to be enlarged. The Sublima mine, 10 miles from Nacozari, is shipping ore averaging 10 oz. silver and 10% copper. Ore from the Cobre Verde, 6 miles from Cobullona, returns 8 oz. silver and 20% copper. Shipments of ore assaying 20 oz. silver, \$1 gold, and 40% lead are going to El Paso from the Nacozari Consolidated mine. A mill is being erected.

Schools and Societies

A School of Mines is to be started at Haileybury, Ontario, in conjunction with the present High School.

The mining engineering department of the UNIVERSITY OF ILLINOIS is adding further rock-drilling equipment to its plant.

The IDAHO MINING ASSOCIATION will meet at Boise on January 20, and important subjects will be discussed. Harry L. Day is president of this society.

The CANADIAN MINING INSTITUTE will hold its sixteenth annual meeting at Montreal on March 4, 5, and 6. Seventeen valuable papers are promised for discussion.

The Southern California section of the AMERICAN INSTITUTE OF MINING ENGINEERS met at Los Angeles on January 15. The subject discussed was 'Geology Applied to Mining.'

The UNIVERSITY OF ILLINOIS is to establish miners' and mechanics' institutes, under the direction of the Department of Mining Engineering. These branches are to prepare men to pass the tests required by the state before they can hold official positions about the mines.

The CLEVELAND ENGINEERING SOCIETY held its regular meeting on January 13, an inspection trip two days later, and a special meeting is to be held on January 20. A week later the semi-monthly meeting will be held, when J. C. Gillette will present an illustrated paper on 'Natural Gas.'

HEALD'S ENGINEERING SCHOOL, of San Francisco, graduates have recently received appointments through the U. S. Civil Service Commission. One is with the topographical drafting office of the Department of War; another is in a similar office of the Department of Agriculture; while the third is in the engineering department of the Department of War.

At the UNIVERSITY OF NEVADA, Reno, an Industrial Safety Conference will be held on January 26 and 27. This will include a number of discussions on the 'safety first' movement, demonstrations, motion pictures suitable for the occasion, first-aid work, and other kindred subjects. There will be an influential and representative gathering of power and mining companies, state officials, and workers in the field.

San Francisco members of the AMERICAN INSTITUTE OF MINING ENGINEERS completed the organization of a local section, January 12, by the adoption of by-laws and the election of the following officers: Chairman, S. B. Christy; vice-chairman, H. C. Hoover; secretary-treasurer, Abbott Hanks; additional members of the executive committee, C. W. Merrill and F. W. Bradley. The meeting followed an enjoyable dinner at the Engineers' Club, at which 34 were present.

The MASSACHUSETTS INSTITUTE OF TECHNOLOGY, Boston, has issued its *Bulletin* of 534 pages, covering the officers and students, statement of requirements for admission, and a description of the courses of instruction. Students must be 17 years of age, and qualified to study the subjects chosen. Courses may be taken in all mining and engineering subjects. Instruction is given in aviation and warship construction. Many scholarships and fellowships are offered to certain graduates.

The MASSACHUSETTS INSTITUTE OF TECHNOLOGY is receiving students from all countries, the latest being two from Russia. From this country they are generally sent by the Russian government, although occasionally they come of their own initiative. An increasing number of students are coming from foreign countries. Additions to the laboratory consist of a Hyde flotation unit, an Elmore flotation test plant, a hindered settling, open-spligot classifier, a Sturtevant crusher and accessories, and a McCully crusher. A Halberger electric furnace of 8-lb. copper capacity is to be installed.

Personal

C. R. CORNING is in Paris.

J. V. N. DORR has gone to Cobalt.

R. M. Nye has been in San Francisco.

E. C. HUTCHINSON was at Jackson last week.

HOMER L. CARR has returned from Colombia.

ROSS B. HOFFMANN left yesterday for London.

A. E. DRUCKER is in Egypt, returning to London.

ARTHUR C. NAHL, of Triunfo, Baja California, is at Berkeley.

W. H. STORMS is in Amador county on professional business.

R. G. CASEY, Jr., sailed for Sydney on the *Sonoma* this week.

S. F. SHAW is temporarily at the Horn Silver mine, Frisco, Utah.

A. C. BOYLE has returned to Laramie, Wyoming, from New York.

C. G. GUNTHER has returned to New York from the island of Cypress.

C. S. HERZIG has removed his offices to 1 London Wall buildings, London.

SIDNEY L. WISE is now associated with the Mines Management Company.

L. C. GRATON is spending several weeks in geological studies at Globe, Arizona.

D. L. C. HOOVER is now with the Cia. Metalurgica Nacional, Matahuila, S. L. P.

LOYAL W. TRUMBULL is now state geologist of Wyoming, succeeding C. E. Jamison.

KARL EILERS is in the West, expecting to return to New York by the middle of February.

T. WALTER BEAM, of Denver, was in San Francisco this week, after an inspection along the Mother Lode.

L. G. HUNTLEY has returned to the Tampico oilfields in Mexico, after spending the holidays at Pittsburgh.

LYOYD B. SMITH has returned from the West Indies, where he has been making examinations of oil properties, and is now in Oklahoma.

C. P. NIELL, former Commissioner of Labor, is now a director of the American Smelting & Refining Co., in charge of safety and sanitation work.

N. H. DARTON made an address on 'Mine Gases' before the A. I. M. E. on January 16, giving an account of extensive investigation of this subject made under the auspices of the Bureau of Mines.

THE properties and departments of the Consolidated Mining & Smelting Co., of Canada, have been in charge of the following gentlemen during the past 15 months, according to the report of R. H. Stewart, the general manager: S. G. Blaylock, assistant general manager; T. W. Bingay, comptroller; James Buchanan, superintendent of smelter; M. H. Sullivan, assistant superintendent of smelter; J. F. Miller, superintendent of refinery; M. E. Purcell, superintendent of Centre Star group of mines; E. G. Montgomery, assistant superintendent; F. S. Peters, superintendent Le Roi mine; C. H. McDougall, St. Eugene and Sullivan mines; K. B. Carruthers, Molly Gibson mine; W. A. Cameron, Slocan Lake properties; and W. M. Archibald, J. M. Turnbull, and A. W. Davis, mining engineers.

Obituary

H. T. CROOKSHANK, an Englishman working in the cyanide department of the Real del Monte mill at Pachuca, was electrocuted recently while throwing a switch.

W. S. COPELAND was killed at Cripple Creek, Colorado, December 19, by falling down the Jo Dandy shaft. Mr. Cope land was well known as a mine manager and owner of sampling works in the district.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter. Total in 1913, 9,100,000 pounds.

ALLOUEZ MINING CO., Allouez, Michigan. \$2,500,000 in \$25 shares; controlled by the Calumet & Hecla, which owns 43,000 shares and \$250,000 in notes of the Company; ore is milled by the Lake Milling, Smelting & Refining Co., in which the Allouez owns half. Total in 1913, 4,200,000 pounds.

ANACONDA COPPER MINING CO., Butte, Montana. \$108,312,500 in \$25 shares; controlled through Amalgamated Copper Co. by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters.

| Zinc dust, 100 kg. zinc-lined cases, 7 $\frac{1}{2}$ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 14.—The copper market is weak and there is little demand for the metal. Lead market is easy, with quotations ranging from 4.05 to 4.10. Spelter is steady with quotations at 5.20 to 5.30. Tin is firm with spot and January quoted at 36.85 to 37.10, March 36.85 to 37.15, and April 37 to 37.37. Antimony is dull, with Cookson's quotation at 7.45 to 7.60. The National Lead Co. reports a normal business for this season of the year, and a dividend has been declared by the Amalgamated Copper Co. Mining stocks in general are up and a greater interest is being manifested.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| June | 17.23 | 14.71 | Dec. | 17.37 | 14.25 |

There was little of interest to record in the New York copper market for last week. Before January 8 everybody was waiting to see what the Copper Producers' figures would be, and after these were published they continued to wait for something to turn up. At the end of the week, 30-day copper was available at 14 $\frac{1}{2}$ c. from the big dealers and at 14 $\frac{1}{4}$ c. from small sellers. Exports of copper for the week ended January 8 totaled 12,689 tons, against 6147 tons a year ago. At this rate the month will show about 100,000,000 pounds. Some of the large consumers venture the statement that a good deal of this metal is merely being sent on consignment, and will soon show itself in increased foreign stocks.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | | Dec. 31 | 40.00 |
|-------------------|-------|---------|-------------------|
| Dec. 18 | 40.00 | Jan. 8 | 39.50 |
| " 24 | 40.00 | " 15 | 39.50 |
| Monthly averages. | | | |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Monthly averages. | | | | | |
|-------------------|-------|-------|------------|-------|-------|
| | 1912. | 1913. | | 1912. | 1913. |
| Jan. | 42.53 | 50.45 | July | 44.25 | 40.70 |
| Feb. | 42.96 | 49.07 | Aug. | 45.80 | 41.75 |
| Mch. | 42.58 | 46.95 | Sept. | 48.64 | 42.45 |
| Apr. | 43.92 | 49.00 | Oct. | 50.01 | 40.61 |
| May | 46.05 | 49.10 | Nov. | 49.92 | 39.77 |
| June | 45.76 | 45.10 | Dec. | 49.80 | 37.57 |

During the past year tin has maintained its reputation as giving one of the most erratic and fluctuating markets in the world. Price changes were, as follows: The year opened at New York with 50.45c. per lb.; the highest price was 50.875c.; lowest, 36.725c.; the term closing at 37c., making an average of 43.6544c. per pound. Supplies were 62,533 tons from the Straits, 3175 from Australia, 14,800 from Banca, and 2200 from Billiton, with 9953 tons standard in United States and England, a total of 92,661 tons. This is an increase of 1914 tons on the previous year. Deliveries were 17,897 tons in London, 15,522 in Holland, 10,283 on the Continent, 43,900 at U. S. Atlantic ports, and 2000 at U. S. Pacific ports, making a total of 89,602 tons, a decrease of 6372 tons. To compute the grand totals of supplies and deliveries, about 25,000 tons should be added to the preceding figures. The visible supply at all points and afloat at December 31, 1913, was 13,893 tons. This year's increase in the visible supply is due chiefly to the smaller deliveries in America, amounting to 5600 tons. L. Vogelstein & Co. state that estimates of the Straits production in 1914 do not show as large an output as in 1913. The last season was the best there for 20 years. All told, the prospects are good for starting a reversal of the statistical position, and even without such reversal, and assuming that all the adverse factors with which the market has contended during the past year were to continue, the visible would only be back to figures at end of 1911 and prices are lower now than then.

Coinage at Mints

The Bureau of the Mint reports the coinage executed at the mints of the United States during the year 1913 was as follows:

| Denomination. | Pieces. | Value. |
|----------------------|------------|-----------------|
| Double eagles..... | 596,338 | \$11,926,760.00 |
| Eagles..... | 508,071 | 5,080,710.00 |
| Half eagles..... | 1,324,099 | 6,620,495.00 |
| Quarter eagles..... | 722,165 | 1,805,412.50 |
| Total gold..... | 3,150,673 | \$25,433,377.50 |
| Half dollars..... | 1,326,627 | 663,313.50 |
| Quarter dollars..... | 1,975,413 | 493,853.25 |
| Dimes..... | 20,270,622 | 2,027,062.20 |
| Total silver..... | 23,572,662 | \$3,184,228.95 |
| Five cents..... | 73,659,239 | 3,682,961.95 |
| One cent..... | 98,437,352 | 984,373.52 |

| | | |
|-------------------------------------|-------------|----------------|
| Total minor..... | 172,096,591 | \$4,667,335.47 |
| Total coinage..... | 198,819,926 | 33,284,941.92 |
| For Philippine Islands government: | | Value. |
| 20 centavos (948,565 pieces)..... | | \$189,713.00 |
| 10 centavos (1,260,693 pieces)..... | | 136,069.40 |
| 1 centavos (5,000,000 pieces)..... | | 5,000.00 |

BANK CLEARINGS in the United States in 1913 totaled \$169,551,826,803, against \$173,952,914,911 in 1912.

The Oil Situation in 1913

According to David T. Day, of the U. S. Geological Survey, operation in other countries in 1913 may be summarized as follows: Prospecting extended to remote regions of South Africa, southern Chile, Patagonia, many islands of the Pacific, China, Japan, and the East Indies. The work of most interest to the United States was that in the West Indies, Central America, and South America, on account of the approaching completion of the Panama canal. In Venezuela, American capitalists were actively prospecting in many regions, chiefly along the northern border. More than 20 field parties were engaged in exploration.

In Colombia, English, American, and Canadian oil interests were concerned with concessions for the development of large areas where, though no large oil wells have been developed, the seepages of oil and asphalt are so significant as to lead to the hope of a large addition to the supply of fuel oil. The Cowdray interests withdrew from Colombia in the latter part of the year.

Delay has been experienced in developing the oilfields of Argentina, owing apparently to the desire of the government to retain the oil as a national monopoly. In Chile a governmental commission examined the oil and gas indications in the Magellan region and made a favorable report. In Ecuador the Cowdray and other interests carried on a vigorous campaign for the acquirement and development of areas showing oil indications in the interior, as well as in the region of the old wells near the coast. Interest was shown in the possibility of finding oil in Panama, Costa Rica, Nicaragua, and Honduras, but there has not yet been time for a significant result. In the islands of the West Indies prospecting for petroleum was active in Haiti, where a small oil well was drilled near Azua. In Cuba drilling for oil was resumed near Havana, Cardenas, and Motembo. Explorations for oil were also active in Barbados.

In Mexico development work was remarkably active considering the unsettled condition of the country, and it resulted in the development of several large wells in the neighborhood of the great gusher at Potrero del Llano. Another large gusher was obtained at Los Naranjos, on the shore of Tamiahua lagoon, which indicated a considerable addition to the total oil supply. The 8-in. pipe-line of the Mexican Eagle Oil Co. was completed from Potrero del Llano to Tampico. The refinery of this Company between La Barra and Tampico is nearing completion. Among many other interesting developments in Mexico was the continued interest in the Topila oilfield, near Tampico, where, in spite of many wells going to salt water, the unusually large gushers occasionally obtained have stimulated continual drilling operations.

A feature of importance for the United States was the development of a large fleet of tank steamers for coastwise and trans-Atlantic trade. Imports of Mexican oil were extended to several refining centres of the United States.

The general interest in the development of new oilfields which characterized the year 1913 extended to Alberta and Saskatchewan, in Canada. Although explorations in Saskatchewan gave either natural gas or else entirely negative results, a well 27 miles southwest of Calgary, in Alberta, struck oil of very light gravity, causing much excitement, and a large territory in that region was taken up by prospectors for oil. This oil excitement extended to the region north of Edmonton, in Alberta, where on Athabaska river and its tributaries large bodies of so-called 'tar sands' have been known for many years. Work has continued in the developing of the natural gas, petroleum, and oil-bearing shales of New Brunswick.

In Russia the production of oil declined significantly in the larger fields, but meanwhile the Ural-Caspian field was actively exploited. This field is reached by steamers to the

north shore of the Caspian sea. Exploration in the Ural-Caspian field north of the present oil wells has been extended over many miles and has shown that the area, while spotted, gives promise of further development. Exploration in this field is impracticable in winter.

In Galicia deep boring is tending to check the decline in the oil supply, and the exploitation has been actively carried forward in all regions where indications have been noted in the past. It is probable that the government of Hungary will develop the gas wells in the region of Kisarmas. In Rumania oil production continued active in spite of the severe fire in the Moreni field. The chief contribution to the industry by the government was the development of a pipe-line system from the producing fields to Constanza, on the Black sea. In Japan production was greatly helped by the introduction of the rotary system of drilling.

World's Production of Gold and Silver, Mint Estimate for 1912

Other countries in the region have also experienced a decline in the number of people living in extreme poverty. In Argentina, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Brazil, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Chile, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Colombia, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Costa Rica, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Cuba, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Ecuador, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In El Salvador, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Guatemala, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Honduras, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Mexico, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Nicaragua, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Panama, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Paraguay, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Peru, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Uruguay, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Venezuela, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In the Dominican Republic, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In Haiti, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In the Caribbean, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In the Americas, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998. In the world, the number of people living in extreme poverty fell from 10.5 million in 1990 to 6.5 million in 1998.

EDITORIAL

DISCOVERY that the hot waters at Idaho Springs, Colorado, contain 25 times the amount of calcium in the springs at Joachimsthal, accounts for the optimism long enjoyed from Idaho, a place that had call that one of Colorado's best loved minor cities.

A NEW editor has been chosen for 'The Journal of Industry,' the highly successful journal founded in 1892 by R. P. Rowland. Mr. G. A. Rees, who takes up the work this year, is assistant professor of metallurgy at Lehigh University and one of the active members of the Electrochemical Society. He is thoroughly qualified for his new duties, and is welcomed by all who read his review of electro-metallurgy in 1911 which appeared January 3. Incidentally, we were in error in stating that he was associate editor of *Metallography* and *Transactions of the American Electrochemical Society*.

EXCESSIVE use of powder underground is to be considered a considerable result of mitherinking habits, as is suggested elsewhere by Mr. R. Noblett. We recall an instance where the miners were told in the faith that four sticks were needed to break each blow. Quiet tests by the engineer and the foreman showed that three would do the work. Thereupon a carload of powder was bought and a new special order so that four sticks contained the same amount of explosive and had properly been put in three. The miners refused to use the cartridges, the reason being as well known and better stated, all too briefly, than to quote the words cited.

CHEAP hydroelectricity power has been a factor for the growth of the pulp and various other manufacturing industries in Norway and Sweden. The analogy between Alaska and Scandinavia is pointed out by the article by Mr. E. P. Kennedy on the Long River power project that we print this week. We published, December 2, 1911, some interesting notes on the situation in Norway and Sweden. Mr. Kennedy proposes to develop power at a cost of \$3.43 per horse-power year, which compares favorably with costs in Norway of \$4 to \$7 and in Sweden of \$7 to \$11. In a subsequent article Mr. W. P. Lass will point out the possible uses of this power. In the meantime, Mr. Kennedy's estimates of construction costs may be received with entire confidence, as they are based upon long personal experience in directing work in the region.

BELIEVING that an ounce of prevention may be better than a pound of damage suits, the Anaconda Copper Mining Company has recently adopted a plan which, it is hoped, will greatly reduce the number of accidents in its mines. The Company offers a prize of \$1000 to the foreman in whose jurisdiction there are the smallest number of accidents during the year, and a second prize of \$250 to the foreman reporting the next lowest number. Surely \$1250 a year could not be spent to better advantage, for the promotion of a keen rivalry between the foremen should result in the instillation of a spirit of carefulness into the miners which will be more valuable than insurance, both to the Company and the workmen themselves.

THE annual meeting of the Mining and Metallurgical Society, held in New York, January 14, was a particularly pleasant affair. Following the usual dinner, informal talks were given by Messrs. Sidney Jennings, Parke Channing, Allen Rogers, and others, and the discussion of the latest things in mining ranged from Alaska to Chile. Mr. J. F. Kemp, the newly elected president of the Society, discussed in his best manner a new method for getting metals out of the ground without mining, and Mr. D. M. Riordan told of early experiences in the Southwest. It was announced that Mr. J. R. Finlay had been elected vice-president, Mr. W. R. Ingalls, secretary-treasurer, and Messrs. J. Parke Channing, Hennen Jennings, P. N. Moore, and H. Foster Bain, councillors.

WASHINGTON dispatches indicate that a lively interest is being taken in the bill now before Congress that proposes to give to the President power to withdraw radium lands from entry and to the Secretary of the Interior to lease these lands or otherwise provide for mining the ores so as to secure needed radium for government hospitals. A vigorous protest against any further land withdrawals has been made on behalf of Colorado, in which state the known lands occur. We printed January 3 an authentic account of the arrangement existing between the Bureau of Mines and the National Radium Institute, which, by the way, draws its ores from lands already in private ownership, and we have also published full details regarding the pitchblende deposits of Gilpin county. In a matter of so much potential importance to human life and health, it is surely better that the technological developments should be public and free to all, as is provided in the present plans of the Radium Institute and the Bureau of Mines. It would also seem good sense, if the Government owns radium-bearing ground and has the necessary technical information, as it presumably will have as a result of the arrangement with the Radium Institute, to reserve a supply of ore for its own hospitals. There are large sources of supply now in private ownership, and the power that it is proposed to give the President would by no means convert Colorado into the howling wilderness that a few of our more excitable friends seem to vision.

Oroville Dredging Limited and Its Future

The resumption of dividends by the Oroville Dredging Company, Limited, and the recent announcement of the purchase of a tract of rich gold gravel land adjoining the Pato property in Colombia, brings this Company into the limelight. The dividend of six pence per share, payable March 1, will gladden the hearts of the many shareholders who have patiently waited for four years to receive some returns on their seemingly unfortunate investment; and a continuation of dividends is to be hoped for, as a result of the satisfactory earnings now being made from the dredge on the Pato property. The California properties of this Company are nearing exhaustion, most of the dredges have had to be abandoned or dismantled, and of the three boats still in commission, there are only two which can be expected to last until the ground can be exhausted. According to a report by Mr. Theodore J. Hoover, dated May 16, 1913, the remaining ground at Oroville will be dredged in five years with a total net yield of approximately \$500,000. Mr. Hoover states that "there is no prospective value in the Oroville business, and * * * the limits of our income and profits are very definitely fixed." Inasmuch as the annual profits after 1913 from Oroville are not expected to exceed \$68,000, it is evident that the shareholders will have to rely largely upon the operations in Colombia for their dividends and the return of capital invested. The revenue from the properties in California since they were acquired in 1905 has been far from satisfactory. Dividends amounting to \$1,383,000 have been paid, and a further sum of about \$500,000 is expected from the yield in 1913 and that of the next five years, when the properties will be exhausted. The total yield, therefore, will fall short of the capitalization of the Company by about a million and a half dollars. The discontinuance of dividends was considered necessary in order to acquire another property from which the inevitable loss on the California properties might be recouped. In 1909, therefore, the Pato property in Colombia was secured, and the earnings from the California dredges for the past four years have been used in equipping the new property.

The Pato concession contains over 20,000 acres, but of this vast area only 310 acres has been proved to contain gold gravel having a satisfactory average value. Mr. C. H. Munro made a thorough examination of this ground and sampled it, reporting the average gold content to be 31 cents per cubic yard. The total net value of the tested area was stated to be approximately \$1,750,000, which amount was expected to be realized in seven years, working with one dredge. Unfortunately, the expenditures have been double the amount anticipated when the property was examined, with the inevitable result that the expected profit from the Pato property will be materially reduced unless further prospecting shall reveal new areas of pay-gravel. Pato has proved to be a most expensive ac-

quisition. On July 31, 1913, according to the Company's published reports, the Pato company's indebtedness amounted to about a million and a half dollars, consisting of the 8 per cent income notes, and interest thereon, due the Oroville Dredging Company \$1,266,000; further cash advances by the Oroville Company (\$118,000); and a loan from the Consolidated Gold Fields of South Africa, with interest (\$151,000). The Oroville company had advanced to the Pato from its own surplus and reserves, and from money which it had borrowed, over \$1,000,000 for the purpose of equipping the latter property. Inasmuch as the Oroville Dredging, Limited, owns 75 per cent of the stock of the Pato company, it is evident that if the profitable ground of the latter should prove to be confined to the 'tested area,' having an average recoverable value as previously determined by the engineers, the Oroville company's share of the profits will come to about \$1,300,000—an amount only slightly in excess of the cash actually advanced. On this basis we find that the total amount of dividends previously paid, together with revenues expected from the properties in California and Colombia, comes to approximately \$3,200,000, as against the Oroville company's capitalization of \$3,500,000. Inasmuch as no disbursements to shareholders can be considered as dividends unless the return of the entire amount of the capital is assured, it is apparent that the payment of actual dividends upon Oroville stock must depend upon the discovery of additional profitable ground in the Company's property in Colombia.

With regard to results at the Pato property, it is interesting to note that actual dredging was not commenced until about February 1, 1913, but the results since then have greatly exceeded expectations. During the six months ended July 31, 1913, about 450,000 cubic yards was dredged with a yield of 14.79 cents per yard at a working cost of 12.49 cents. The latter figure, it is to be noted, is based upon six months only. The ground dredged was below the tested area, and supposedly barren, so the results were unexpectedly encouraging. After August 1, when the tested area was reached, 458,000 cubic yards was excavated, which contained an average of 74.15 cents in gold per cubic yard. The yield was more than double the average value calculated from the results of drilling the 310 acres in question previous to the purchase of the property, and from this fact some have been inclined to infer that the original estimates of the engineers were far too low. Such an assumption is unfair both to the engineers and to the shareholders, for it is well known that the richer gold gravels are usually found in well defined channels or in certain areas of limited extent, and the gravel now being dredged may well be in a channel where the gold content is higher than the average of the whole tract. Mr. Munro, after a thorough examination of the ground, calculated an average value of 31.31 cents per cubic yard. From our knowledge of the accuracy with which gold grav-

els can be tested, and the undoubted ability of Mr. Munro, we believe that the dredging of the entire 310 acres will prove Mr. Munro's figure to be very nearly correct. The dredging of ten or fifteen acres of 74-cent gravel at this time merely means that the recovery from the rest of the gravel area may be considerably less than 31 cents per yard. It is evident that the dredge is now digging some of the best ground the Company owns. The fact that the few acres already dredged contained twice as much gold as the average calculated by the engineers most assuredly does not prove that the higher value per yard will be found throughout the entire extent of the tested area.

With respect to the prospects of finding additional areas of dredgable gravel on the Pato concession, Mr. W. A. Prichard is reported to have cabled that the concession is now found to include nearly 40,000 acres; that California hill is of small area, and the gravel there averages 12 cents per yard; and that there are other placer deposits on the Pato property which are "well worthy of investigation." It is extremely gratifying to know that the territory is so vast, and it is to be hoped that it may be found to contain many good placer deposits, but the fact remains that the Pato property is merely an undeveloped prospect except for the tested area and California hill. At the latter place the drilling has not proved gravel containing a very satisfactory amount of gold, for it is not probable that a limited area of 12-cent gravel can be worked at a reasonable profit. The value of the concession, beyond the tested area, therefore, is entirely prospective and speculative. It is quite possible that systematic prospecting and drilling may reveal valuable gold gravel deposits in other parts of this enormous property, and we sincerely hope that this may be the case, but at the present time there seems to be little definite information upon which to base the rather optimistic reports which are now being circulated.

The most recent announcement contains news which is surely intended to fill the hearts of the shareholders with hope, and to advance the price of the stock. It is stated that the San Francisco property of 400 acres, adjoining the Pato on the other side of the Nichi river, has been purchased for the trifling sum of \$51,000, and that from the results obtained by drilling, Mr. Prichard has proved 90 acres of pay gravel, averaging 70 cents per cubic yard, with a depth of 48 feet. Mr. Hoover calculates that, if these results are confirmed, the area should yield a profit of about \$3,500,000, after allowing 10 cents per yard for operating costs, and about \$500,000 for equipment. It must have startled the Oroville directors to learn that a veritable bonanza had lain almost at their doors for four years, perhaps quite unsuspected; and that this could now be purchased for a song! However, they bestirred themselves sufficiently to keep the cables hot until the money was transferred before the option had expired. We congratulate the Company, and trust that the reports may in due time be fully confirmed.

What is the Matter With Prospecting?—III

A SYMPOSIUM*

Charles A. Chase:—I think that money is available in reasonable amounts for finding and developing prospects. One comes across many groups of people in this state (Colorado) who are doing some exploration and some development. I think that additional money will be found when prevailing conditions are better. Government aid does not seem to be necessary at this time. It seems to me that the answer to the questions regarding prospecting conditions is suggested in your first paragraph, in which you say that we will come to a metal famine. If we do approach a metal famine, I am sure that with rising prices large amounts of new money will be available for new work. It seems to me that this is the logical answer to your whole letter.

Coal Engineer:—I should say that, leaving aside current monetary conditions occasioned by national legislation and uncertainties, "money is readily available in adequate amounts for finding and developing prospects," though capital expects the major portion of the profits through majority of stock ownership. The man who wants all cash for his prospects and retains all the stock ownership of the resultant successful exploitation is not welcome at the feast! It is, of course, difficult to get money readily in any considerable quantity because of the highly speculative nature of most of the undertakings; but money is available, I believe, for legitimate mining enterprises, endorsed by reputable engineers. I think it might be made more available if actual conditions, risks and returns, could be plainly shown and truthfully manifested. I do not believe in government aid to prospectors, except through the publications and maps of the Geological Survey. Prospecting methods have necessarily been improved as the more conspicuous deposits have been discovered and developed; but the expense of prospecting has correspondingly increased. A better market for undeveloped mineral lands might possibly be created by educating capital toward securing really competent specialists to report on undeveloped mineral lands, not merely from the technical standpoint of the government geologist, but from that of the commercial engineer to whom capital looks for its safeguards and returns. This would tend to reduce risks and create better public sentiment.

*[In presenting this third of the series on 'What is the Matter with Prospecting,' the first of which appeared in the 'Annual Review Number,' we would state for the benefit of those who did not see the first of the series, that the content of this symposium has been abstracted from letters received from some of the best informed members of the profession. Upon this subject of importance to the mining fraternity, we take pleasure in thus presenting their individual viewpoints.—EDITOR.]

Stanly A. Easton:—I believe that there is just as much money now available for finding and developing mining prospects as ever before. In fact, I am inclined to think that there is a good deal more money available. I do not believe in government aid to prospecting and prospectors—that is, direct financial assistance. The art of prospecting can be encouraged by the Government by giving the prospector a free hand and assuring good treatment to the prospector and those backing him in their first search, and in the work following upon a discovery. Further prospecting must be accompanied by a great deal more development work than heretofore. The big, prominent, rich outcroppings have all been found in every country that has even been partly explored. What is required now is prospecting by development work, either by churn-drilling, sluicing by ditch or pressure, or shaft, or tunnel development, and in connection with the most careful study of the areal geology. In order to justify such expense and labor, the locator and his associates must know they will not be disturbed in possession of the ground they are investigating and must feel that if they succeed in disclosing mineral of value, they will be able to get title from the Government to enough area to protect them from litigious neighbors. The principal requirement above public interest, financial backing, or other factor, is the protection of the prospector and his associates in their possession and development of the land, by providing some method by which title to undeveloped and partly developed mineral land, or land which is sufficiently promising in mineral possibilities to justify serious investigation, can be safely and surely secured. While it is true that no new districts are being advertised at this time, still it will be found that around such big mining centres as Butte or the Coeur d'Alene, new mineral bodies are being continually opened, not only in new properties, but in the extensions of the workings of the older mines. These new developments add vastly to the mineral resources of the country, but are not advertised; nor, in fact, is anything known of them except to those directly connected with the work.

F. Lynwood Garrison:—It is certainly not true that money is no longer available for finding and developing prospects; quite the contrary, in fact, for in my opinion there is more money to be had for this purpose than ever before, and will continue to be as long as the gambling spirit is in human nature. The thing is to take advantage of this trait and see that it is wisely and effectually directed. This money can be made available by proper representations regarding the prospect, claim, or mine, as the case may be. But

this information should be obtained by a skillful and trustworthy mining engineer, or by one whom he knows to be competent and reliable. It is preferable, however, that the engineer himself should have examined the property. The only way the Government is likely to be able to help prospecting and prospectors is by having better mining laws. It has done, and is still doing, much through the Geological Survey in the way of providing reliable maps and other data. Prospecting methods and conditions certainly can be improved, and naturally such betterment would be most quickly effected if the work were in the hands of a competent mining engineer. A better market for undeveloped mineral lands can be created by a stronger public sentiment against fake promotions and charlatan engineers and geologists. The postal laws are always be invoked to check this kind of fraud, if people would take the trouble to go to the proper authorities with well assured facts. In an opinion, fraudulent promotion in metal mining has been a great deterrent to the legitimate development of the country. Of course, dishonest mining is a matter of existence if there were not so many foolish and avaricious people with money ready to pay for such schemes. We cannot hope to eliminate this kind of fraud, but we can make it very bad for the promoters and the public.

Andrew C. Lawson:—It is my impression that the ancient and honorable profession of prospecting is suffering from atrophy. It is an old profession, but the reason for this is that the prospector does not get his proper share of the value of his prospect when it proves to be valuable. It requires capital to make a mine out of a prospect, or even to develop it to that stage at which the probability of its having the makings of a mine becomes apparent. Money is as a rule spent freely on prospects only where these have high grade ore, or where, if the ore is low, a vast tonnage is in evidence at the surface. The only way of securing money for the development of a large proportion of these prospects is the organization of prospecting and development companies to engage in the business of mining venture, as distinguished from buying a sure thing. It is my belief that if such companies were to act on competent advice, so as to minimize the chances against them, their winnings in the long run would be large, and these should be shared with the prospectors who make the lucky finds. I do not believe in government aid to prospecting and prospectors. I believe the time has come when prospecting may be done on geological principles, to a very considerable extent, along lines that are impossible for the ordinary prospector; but the highest geological skill will be required for the direction of such work, and many blanks will be drawn for one prize. A better market for undeveloped mineral lands would be secured: (1) by the suppression of fake mining companies which undermine the public confidence in mining ventures; (2) by disposing of mineral lands by lease only; (3) by systematic exploration of such lands

by prospecting and development companies so that their value may become known; (4) by improving transportation facilities in new districts; (5) by encouraging the development of agricultural and other industries in mining districts to the end that they become stable instead of ephemeral communities; (6) by doing away with the apex law so that costly litigation may be minimized and greater security of tenure obtained; (7) by the extension of geological surveys in greater detail than has hitherto been customary.

Mining Engineer:—As far as the writer's observation extends, it is true that money is no longer available in adequate amounts for finding and developing prospects as regards the outside public, but this does not apply to the majority of those actively and continuously interested in mining affairs. There seems no possible way of renewing interest which shall show itself in a readiness to furnish additional money for such purposes save by either (a) a largely increased price in metals which shall make profitable many small mines now unworked, or (b) a recurrence of that psychological condition known as a 'mining boom.' Under no conditions is aid to prospectors a function of the Government. Such aid would result in abuses of the worst form with no satisfactory returns. There are thousands of prospects throughout the United States which would find development if the owners did not demand outrageous prices for them. The actual chances for the old-fashioned prospector are by no means what they were in the days of the earlier mining booms. The time has come for capital, wisely directed, to assume some of the risks of prospecting and development; but, naturally, capital does not stand ready to do this if in addition to the inevitable prospecting risks it must pay unreasonable prices or assume unreasonable contracts on undeveloped properties. After all, possibly a good dose of hard times may be the best cure for all this gold fever. A cure of this sort is even now in progress in the Leadville district, where a familiar process is being repeated. That district is well known as the 'Poor Man's District.' Whenever the price of zinc ore reaches a level unprofitable for the low-grade mines, so that wage-work is scarce, the miners turn to prospecting by leasing, reasonably sure that the chances for finding some mineral are worth taking. New discoveries are being made from week to week in that district, and when the price of zinc ore again advances, it is a reasonable expectation that there will be a number of new large producers as the result of the present stress. In a general way this same condition may follow throughout the whole country.

W. Lindgren:—I emphatically do not believe in government aid to prospecting and prospectors except in the line of improving communications in the wilder and more distant regions.

R. A. F. Penrose, Jr.:—I believe there is plenty of available capital for developing mining prospects when

it is to be used legitimately and is not to be handicapped by too much legislative interference. It was the encouragement given by our Government to the honest effort of individuals, that originally developed and fostered the mining industry of the West. If we attempt to interfere with this by too many restrictions, I think we will find that prospecting and the development of mines will lose much of their old activity. I believe that the federal and state governments can do much good for the miner in making geological surveys and topographical maps, but I do not think that they ought to exercise too much paternalism over the individual who is legitimately trying to succeed by his own efforts. I do not believe that the Western miner wants to be patronized in this manner. Give him his freedom of action in his honest efforts and he will generally make good without having to be taken care of.

Wm. Fleet Robertson:—The question as to whether new mines are being found as rapidly as is necessary to keep pace with the demand for the metals is, it seems to me, best answered by the prices of the metals on the markets; and as there is no great upward tendency over any extended period, the answer seems to be in the affirmative. The following answers to your stated questions can only be assumed to be of local application to British Columbia. In my opinion it is not true in a general sense that adequate amounts of money are not available for prospecting. Such an investment is naturally a 'speculation' and in recent years the great increment in land and timber values has absorbed the larger part of the speculative money here, with resulting diminution of speculative money for prospecting and developing of prospects. A reaction is now automatically setting in, and mineral property will soon again receive its legitimate amount of speculative money. The picturesque prospector of the street or saloon has been largely replaced by a much less noisy, better-equipped individual who has his business associates, before whom he lays his prospects. It is simply a change of method, which you may call the effect of civilization, or civilization, as you choose. Many big companies and financial syndicates maintain a staff of junior engineers and mine examiners ready to examine anything reasonable. The large companies in British Columbia will send an engineer to make at least a cursory examination of almost any sort of a prospect presented by a prospector. Government aid cannot be given as financial aid to individuals or properties, as this would be open to the suspicion of government favoritism, and also because such aid would in many cases be abused. Government aid may properly consist of: (a) making trails and roads to facilitate access to districts, including bridging of streams and arranging for ferries; (b) facilitating the easy acquirement by prospectors of claims at nominal cost, with security of titles. In British Columbia a prospector may stake and record a claim 1500 by 1500 ft. (about 52 acres) for \$2.50.

This record holds the land for one year, and if during that year \$100 worth of work is done on the claim and recorded, for a fee of \$2.50 the title is renewed for another year, and so on from year to year. When \$400 worth of work has been done, and a survey by a land surveyor has been recorded, a Crown grant (equivalent to a patent in the United States) can be obtained for \$25. This title is unassailable, excepting by the Government on a charge of fraud. If the property is worked to the extent of \$200 a year it is exempt from all taxation. (c) By having vertical boundaries to mineral claims, and no extralateral rights to tempt litigation to freeze the poor man out. (d) Exploratory work in new district with published reports on the same to indicate likely areas for the prospector to investigate. (e) Free qualitative determinations of all minerals sent in, and advice as to the advisability of making exact tests on the same. (f) Advice in the office and field to all wishing information in mining matters. These aids are all given in British Columbia. A better market for undeveloped mineral claims can be created by restoring confidence in the veracity and ability of the prospecting class, sadly shaken in past years. The public has found by bitter experience that mining is used as a cloak to cover a multitude of swindles, and in consequence people are getting very cautious. The unscrupulous middleman is more to blame in this respect than the prospector. The prospector should be educated as to the true value of a prospect, so that the price asked therefor would not be prohibitory to any sane man intending to develop it. This can be done only by making him realize fully the risks of loss that are undertaken by the purchaser.

W. H. Shockley:—My experience is that none of the larger exploration companies, or important mining companies who are looking for mines, will furnish any money for prospecting. This is also true of the individual capitalists with whom I am acquainted. And I might as well have said at once that I do not know any source from which a prospector can get money for developing a prospect. I do not know any way in which money can be made available, except by raising it by taxation. I see no special need of giving prospectors government aid at present. I do not think it possible to improve prospecting methods or conditions to make the available funds adequate. I see no way in which a better market for undeveloped mineral lands can be created.

Henry W. Turner:—In my opinion it is a fact that money is no longer available in adequate amounts for finding and developing prospects. No doubt additional money could best be made available by showing directors and heavy investors that it costs less to get good mines by trying and developing promising prospects than it does by paying large prices for developed orebodies, with the attendant heavy expenses for examination. Only by developing will the present large companies of the world be able to keep up the

metal production. I do not think that government aid to prospecting and prospectors is at all necessary. A better market for undeveloped mineral properties could be created if the Government would give a special concession of time, say six months, to companies or individuals for prospecting mineral lands, as is done in Mexico. If the prospector were assured possession of his ground for prospecting purposes for a reasonable period of time, no doubt more prospecting would be done.

Horace V. Winchell:—It is true that funds are no longer available for prospecting and developing mining properties. Additional money is not likely to be available until the law is changed so as to give exclusive possessory title to the locator and prospector during the time in which he is trying to make a discovery. I do not believe in government aid to prospectors. Prospecting methods and conditions can be so improved as to make available funds adequate. Undeveloped mineral lands will be in greater demand just as soon as there is such a change in the definition of what constitutes mineral lands as to make it possible to hold them in advance of the actual discovery of ore. While the fundamental defect lies in the law, which at present requires a discovery before completing a location, and therefore before exclusive possession is acquired, still I believe that another fact detrimental to prospecting is found in the creation of so-called 'development companies.' As a rule, these companies are not 'development' companies in any sense, but more properly 'retardation' companies. Before their organization there were numerous individuals of means who were open to propositions from prospectors and the owners of mining properties and who would investigate, through the agency of some mining engineer, propositions which appealed to them individually. There was thus a rather widespread and numerous clientele or purchasing power scattered throughout the land. Each 'development company' gathered a group of these individuals into its fold and made one purchasing entity instead of many. Each 'development company' further employs a consulting engineer or manager to decide upon the purchase or rejection of properties offered to it. These supervising officials feel it necessary to be doubly cautious in accepting properties, and, acting in responsible capacities, will actually not take the chances on behalf of their employers which they would be perfectly willing to take as individuals. They are constantly looking for bargains, and no proposition ever comes to them in an entirely satisfactory form. In order to earn their salaries they must make better terms upon every property brought to their attention. They even go further and actually, although quite probably without realizing it, constitute a little monopoly upon the purchasing side—so much so that if one of these companies learns that another has examined a certain property and failed to purchase the same, the other almost invariably promptly rejects it without any consideration.

Gold in the Canal Zone

A number of placer claims located along the Gatun river and its tributaries, some of them within and some of them without the Zone, have been examined by D. F. MacDonald, the official geologist. The following is a summary of the investigation, as published in *The Canal Record* of November 26:

| Location. | Number of pans washed. | Gold per cu. yd., cents. | Cost of working gravel, per cu. yd. |
|---|------------------------|--------------------------|-------------------------------------|
| Guineal creek | 17 | trace | \$1.00+ |
| Palenque creek | 30 | 2.1 | 1.00+ |
| Cuatro Calles creek | 20 | 0.7 | 1.00+ |
| Quebrada Pato | 22 | 0.6 | 1.00+ |
| Quebrada Mollejones..... | 12 | 2.0 | 0.12+ |
| Agua Clara | 52 | 2.0 | 0.12+ |
| Main Gatun river | 46 | 1.0 | 0.12+ |
| Bar near mouth of Agua Sucia creek | 6 | 7.5 | 0.12+ |
| Another part of same bar..... | 6 | 1.2 | 0.12+ |
| Agua Sucia creek | 47 | 0.0 | 0.60+ |
| Main Gatun, below mouth of Agua Sucia | 28 | 1.3 | 0.12+ |
| Quebrada Lopez | 14 | 2.7 | 0.60+ |

Mr. MacDonald is of the opinion that the territory has practically no value for mining purposes.

Electric Furnaces for Steel Production

A Pennsylvania concern has recently ordered from Siemens & Halske, of Berlin, two 20-ton induction furnaces of an improved type that has been developed from the combined patents of Kjellin, Rochling-Rodenhauer, and Frick. These furnaces, which are now in course of construction, will be of the double-ring form and will be supplied with power from separate single-phase alternators. The generators will supply a current of 5000 volts. The normal power consumption of the furnaces will be 1800 kw. each, and they will be employed for the refining of molten open-hearth steel, which will be used chiefly for the production of rail material. The output of each furnace will be about 160 tons per day of 24 hours, depending upon the grade of steel produced. The importance of this order will be more thoroughly understood when it is considered that up to this time the largest furnace of this type had a capacity of only 12 tons per day. The confidence of the builders is such that they are now offering furnaces of 40 tons capacity, built upon the same lines.—*Daily Consular Report*.

Working with one furnace for 298, and a second furnace for 90 days of the first 11 months of 1913, there was smelted at Katanga, Africa, 48,500 tons of ore averaging 15 to 16% copper and yielding 14,124,000 lb. of copper, at a cost of 9.7c. per pound.

Two reservoirs are being constructed in the state of Hyderabad, India, which will have a total capacity of 13,739,000,000 cubic feet.

Recent Advances in the Study of Sulphide Enrichment

By C. F. TOLMAN, Jr.

Almost simultaneously, Van Hise, Weed, and S. F. Emmons¹ announced the theory of 'secondary sulphide enrichment,' and explained the processes and described the details so accurately and fully, both Weed and Emmons giving illuminating examples from mines with which they were familiar, that the active study of the succeeding twelve years proved to be largely confirmatory and added but little to the deductions of the men. The principle was so clearly announced, easily understood, and well fortified by indisputable examples, and fitted in so well with Van Hise's ideas of the predominant rôle played by the ordinary meteoric circulation in the formation of ores, that it came to be given recklessly as the explanation of all rich sulphide ores found near the surface.

Studies by Spurr at Tonopah, of Lindgren and Ransome at Cripple Creek, and others, proved that bonanza silver ore in combination with sulphur, arsenic, and antimony, and rich telluride ores, often show no notable downward enrichment, and emphasized the fact that field and mineralogical studies were necessary in order to determine the importance of this process. This need induced Ransome to summarize the criteria available for the recognition of 'downward sulphide enrichment', and while the paper, and the discussion which followed, were disappointing in that they did not result in important contributions to our knowledge of the subject, they were of great value in summarizing and coördinating the data at hand. A summary of the process written at the close of 1912, would have read about as follows:

The descending solutions are strongly acid from the oxidation of the pyrite. They contain the sulphates of those metals that appear in the original ores. Solutions of silver and copper producing the most important enrichments. When these solutions reach the water-level they deposit simple and nearly pure sulphides in the reverse order of their solubilities, silver sulphide first, copper sulphide, chalcocite, next, with subordinate amounts of bornite and chalcopyrite in some few cases. Covellite is considered as an oxidation product of chalcocite, or possibly, in a few cases, precipitates directly as a secondary sulphide, at the top of the enriched zone. It is recognized that complex sulpho-salts of silver are often secondary, but the reactions by which they are formed are not understood, and no microscopical study of the opaque sulphides has been made, and therefore the criteria for distinguishing primary from secondary ores are not developed.

At the time the above summary is supposed to have

been written, most investigators thought chalcocite to be formed only by secondary enrichment processes. For example, Ransome stated in his article on the criteria of downward sulphide enrichment: "I believe that we are justified in regarding chalcocite very rarely, if ever, formed except under conditions of downward sulphide enrichment or by vadose sulphate solutions." Although Tolman, in 1907, had explained that there was a rapid neutralization of the acid solutions, and suggested neutral or even alkaline solutions as agents causing the secondary transport of copper, the possibilities along these lines were not recognized. Bard, for example, suggested that calcite gangue tended strongly to inhibit enrichment by the neutralization of the acid and precipitation of the metals as carbonates.

Chemical Research

Although much valuable chemical research was undertaken previous to 1913, about all that was established was that secondary sulphides had been produced by several methods in the laboratory. It could not be said which of these methods, if any, represented the reactions in nature, and the equations governing them were guessed at, rather than known. In fact, the experiments, as reported, were distinctly misleading in suggesting that we had to do with the precipitation of a single stable sulphide, and not, as will be indicated later, a mixture of unstable compounds, changing from one mineral to another, the intermediate and final products being determined, probably, by the composition, and the concentration of the solution, and the temperature and pressure under which the reactions took place.

Before considering the advances in our knowledge of this subject during the past year, it seems advisable to call attention to two things that have proved to be a distinct hindrance to the study of the subject. The first is in regard to nomenclature. It would be difficult to invent a more inappropriate and inaccurate name for the process than 'secondary sulphide enrichment.' Sulphide enrichment alone is probably too narrow a term, for recent experiments and observations show that native silver and possibly native copper may be precipitated in the sulphide zone, and therefore are not merely products formed from the direct oxidation of the sulphides. There are two processes that are contrasted and which need separate terms: (1) downward enrichment caused by descending surface waters; (2) upward enrichment caused by a renewal of the ascending thermal solutions. Secondary is a term used by mineralogists to designate a mineral or minerals formed by the breaking down, replacement, or substitution of an earlier formed mineral. Downward en-

¹For literature on sulphide enrichment, see Tolman, C. F., *Mining and Scientific Press*, Vol. 106, pp. 179-180 (1913); Emmons, W. H., *Bull.* 529, U. S. Geol. Survey, 1913.

richment is by no means always secondary, for chalcocite has been described as filling veinlets in the original ore, and in the country rock. Ascending enrichment is not necessarily primary. A. F. Rogers will describe a well established case of ascending secondary enrichment, in a forthcoming number of *Economic Geology*, and the microscopic study of polished sections of many varieties of ores leads me to believe that there is a break-down in certain primary ores, not caused by descending solutions.

That ascending solutions may react on earlier formed sulphides to form secondary sulphides is not recognized by Graton,² who states: "In this paper, minerals called primary are regarded as products of original deposition from solutions probably ascending, heated, and of alkaline character; secondary sulphide minerals are those produced from other sulphides by the action of descending, cold, acid (or possibly neutral) solutions." This has led him to postulate as a general occurrence a single period of formation of primary ores, and to attribute all secondary changes in these ores to the results of descending vadose solutions; a conclusion which I suspect will be modified by his further studies.

'Upward' and 'Downward' Enrichment

The terms 'upward' and 'downward' enrichment may be applied, then, whenever the origin of the solutions is in mind, and the adjective primary or secondary can be added to either of these terms only when it is wished to emphasize the mode of precipitation, that is, whether the minerals are deposited as a filling of a fissure, or as a replacement of the older sulphides. The terms 'primary' and 'secondary' would be satisfactory to the scientist, but these derivatives of a dead language are hardly well enough to stand rough usage in mining camps.

A. F. Rogers will discuss this case in a forthcoming number of *Economic Geology*.³ He will suggest the terms 'upward secondary sulphide enrichment,' 'upward primary sulphide enrichment,' and 'downward secondary enrichment.' These expressions seem cumbersome, but it seems to me that to use the terms 'upward sulphide' and 'downward sulphide' enrichment to designate the source of the solutions, this will help to divorce the general meaning from the term 'secondary sulphide enrichment,' and we will gradually come to use this expression in its geological sense. It would probably not often be necessary to use the complete term 'downward secondary sulphide enrichment.'

The second point that seems to me to deserve criticism is the assumption that has been adopted in much of the recent experimental work, that the composition of the ore-forming solutions, both ascending and descending, can be approximated from the analyses of mine waters.

Any extensive set of mine workings opens up large

masses of sulphide ore to the direct attack of moisture plus oxygen. This attack is so intense that mine fires are developed at times. Stopes filled with broken low-grade ore expose immense areas of ore to this attack. On the other hand, the underground circulation, given constant head by pumping or tunnel drainage, is made many thousand times more active. The first effect is to manufacture acid, and much later to take the metallic salts in solution. It seems probable, therefore, that the descending solutions that caused enrichment are, in general, much less acid than the present mine waters. The fact that great volumes of water are developed by pumping does not prove that a rapid or copious downward circulation existed before the workings were driven. These earlier downward-creeping solutions, although less acid than those of the mine, may have had a much higher metallic content.

If caution must be used in making our deductions as to the composition of the descending ore solutions from analyses of mine waters, much greater difficulties are encountered in attempting to determine the nature of ascending ore solutions from such analyses. The original ores are probably formed in a brief period of intense mineral activity, and later ascending waters may not give an idea of the composition of the ore-forming waters. Again, most ores are deposited from solutions at considerable depth, and the latter must be different in composition and concentration from the later superficial spring water. This cannot be discussed in detail here, but it may be noted that extensive sets of analyses of mine and spring waters are being collected "with a view of ascertaining the general nature and composition of the waters that have been assumed to be agents in the deposition of lode ores, in order that chemical experiments designed to illustrate the natural processes might be successfully conducted, as far as practical, under natural conditions."⁴

The development of the chalcocite disseminations and chalcocite deposits of the Southwest, the evident relation of enrichment to porphyry and stockwork, and the relation to present and past topography, as the result of erosion, etc., and the effect of the streaks of minerals on the surface of the chalcocite disseminated sulphides at depth, encourage the application of geochemical field and microscopic methods of examination to these deposits. One of the advances that may be credited to 1913 is the recognition of the paramount importance of these relations. Early in 1913 I published a brief summary of secondary enrichment,⁴ emphasizing these relations, and giving examples of practical problems that had been encountered in this work. Shortly afterward, W. H. Emmons' comprehensive treatment of the subject appeared, in which these relations were considered, but the emphasis was

²Emmons and Harrington, 'A Comparison of Waters of Mines and of Hot Springs,' *Econ. Geol.*, Vol. VIII, p. 653 (1913.)

⁴Bibliography and summaries of the papers mentioned will be found at the end of this paper.

placed upon the mineralogical composition of the original ores, and its effect upon enrichment.

Important advances were made in the knowledge of the chemistry of downward enrichment in 1913. Palmer and Bastin determined quantitatively the reaction between silver sulphate solutions and niccolite, throwing much light on the formation of native silver by descending solutions. Palmer and Bastin, and also Cooke and Grout, showed that native silver, and possibly native copper, are precipitated by descending solutions, especially in presence of ferrous sulphate, and we may conclude that the native copper, so often formed toward the top of the sulphide zone, may be deposited directly from descending solutions.

Up to 1913 it was assumed rather generally that the descending solutions causing enrichment were acid, and that the secondary sulphides therefore were precipitated in an acid environment. Grout, however, found difficulty in precipitating sulphides on other sulphides in acid solutions, but obtained rapid precipitation when he mixed solutions containing metallic salts with solutions of alkaline carbonates and hydroxide, that had been in contact with pyrite. He concluded that secondary sulphides are formed by descending acid solutions meeting alkaline solutions. This generalization is, however, somewhat doubtful. It seems probable that in fractured lodes, where a relatively strong descending circulation is developed, an acid condition will obtain. The development of alunite and kaolin by the action of the descending solutions that precipitate the secondary sulphides is evidence to this effect. Moreover, the sulphides generally develop at the underground water-level, and an immediate neutralization at that point does not seem probable. In experiments now being carried on in the chemical laboratories of Leland Stanford Junior University, Mr. Clark has succeeded in obtaining relatively rapid sulphide precipitation when the sulphides are ground fine. However, the neutralization of the solutions is probably an important factor in the precipitation of the later sulphides, and there is a possibility of a rather deep downward migration of the metals in alkaline solutions. We need further experimental work on these problems.

The suggestion of Bard⁵ that calcite gangue tends to inhibit downward enrichment does not find confirmation in the experimental work of Bastin and Palmer. Moreover, many cases of sulphide enrichment of copper ores in limestone are known. On the other hand, lenses of rich oxidized copper ores in limestone occur, which show no leaching of the copper. The reasons for these differences have not received full explanation.

The discovery of the occurrence of important bodies of 'primary' (formed by ascending solutions) chalcocite did not occur in 1913, but the completed proof from structural and field relations was made avail-

able in this year in the valuable contribution of Sales.

The most important development of the study of sulphide enrichment of last year was the demonstration of the value of microscopic study of polished opaque sections of the ores. This study has been carried on for some time at several American universities, but Graton and Murdock have been the first to make public their results in regard to sulphide enrichment.⁶ They show that any of the copper sulphides may be primary or secondary (in the mineralogical meaning), and that secondary changes show a tendency to transform the iron-rich copper sulphides through the intermediate sulphides into the copper-rich sulphide chalcocite. This break-down has been proved experimentally in the valuable contribution of Spencer. As criteria for primary chalcocite, Murdock and Graton suggest cleavage, and graphic intergrowth of bornite and chalcocite. I believe, however, that the criteria in regard to cleavage need verification; that the so-called graphic intergrowth of chalcocite and bornite is certainly in some cases a break-down of some copper sulphide mineral into chalcocite and bornite, and in other cases a replacement of bornite by chalcocite according to a regular pattern.

In the experiments mentioned above, Mr. Clark has been able to prove that the copper sulphides formed in a number of his experiments consisted of a mixture of cuprous sulphide, cupric sulphide, and sulphur. Mixtures of the two sulphides occur in nature, and have been described under the names diginite, carmenite, and harrisite. It seems probable that not only the composition of the original precipitates, but also of the sets of minerals that are developed by the crystallization of this product, are determined by the composition of the solutions and precipitates, and the conditions of temperature and pressure under which they are formed. It is likely, therefore, that the final solution of many of these problems will be accomplished by physical chemistry. We may hope for valuable information shortly from the physical chemists now investigating these subjects.

Bibliography

BASTIN, EDSON S. 'Metasomatism in Downward Sulphide Enrichment.' *Econ. Geol.*, Vol. VIII, pp. 51-63 (1913).

A summary of the results of the study of polished sections of secondary silver ores. Polybasite, proustite, and stephanite are commonly developed by the processes of secondary enrichment. Drawings are given illustrating the

⁵This study is in its infancy, but we may now expect its rapid development. It starts where the examination by transmitted light stops, and shows, in a beautiful way, the relations of intergrowth, replacement, and order of formation of the opaque ores. More attention has not been given this work, perhaps, because of the general idea that the process of polishing is a delicate and tedious one. We have found in our laboratories at Stanford University that the polished surface can be prepared rapidly and easily. A little care will prevent scratching of the surface by coarse powder or fragments of the ores, and a brilliant burnish is quickly obtained by polishing with tin oxide on felt. A section can be prepared in about 15 minutes.

COOKE, H. C. 'The Secondary Enrichment of Silver Ores,' *Jour. Geol.*, Vol. XXI, pp. 1-29 (1913).

Cooke oxidizes, dissolves, and precipitates silver minerals in an instructive series of experiments. He concludes that ferric sulphate is the agent that oxidizes and dissolves the silver, and by reversible reaction ferrous sulphate re-precipitates the native silver. When hydrogen sulphide is present (from the action of sulphuric acid on primary sulphides) this is acted upon by the ferrous sulphate, and sulphur is produced, which unites with the silver to form sulphides. Although not mentioned by Cooke, it is probable that the sulphur necessary for the formation of silver sulphides is also furnished when the solutions attack the di-sulphide of iron, pyrite. Cooke concludes that only in pyritic lodes will enrichment of silver be important. Bastin, however, believes that scarcity of pyrite and abundance of calcite are factors favoring the development of secondary silver sulphide. Cooke also investigates the solubility of silver chloride in salt solutions. The solubility is small in dilute salt solutions, but increases rapidly in concentrated solutions, from which the silver chloride (cerargyrite) precipitates on dilution. This explains the erratic occurrence of bunches of superficial silver chloride in arid regions, for very concentrated salt solutions may develop at or near the surface in desert regions.

EISING, MORRIS T. 'Relation of Outcrops to Ore at Cananea,' *Eng. & Min. Jour.*, Vol. 95, pp. 357-369 (1913).

A study of outcrops and their relation to enrichment. More definite results might have been obtained with assistance of microscopic study of ores and rocks.

EMMONS, W. H. 'The Enrichment of Sulphide Ores,' U. S. Geol. Surv., *Bull.* 529 (1913).

The most important and only exhaustive treatment of the subject that has as yet appeared. The treatment of the relation of enrichment to erosion, physiography, and climate, is less complete than could be desired, when one remembers the control these factors exercise over the processes of downward enrichment. The chemistry of the process is well summarized, and the composition of mine waters is elaborately discussed. One of the most important contributions appearing in this volume is the proof that the vertical range of the secondary sulphide zone shows a relation to the mineral composition of the ore. He states "that ores containing abundant pyrrhotite are not enriched to depths so great as those containing pyrite and chalcopyrite." The author discusses in some detail the mineralogy and paragenesis of the oxidized ore minerals and the secondary sulphides. Unfortunately, he did not have at hand the recent data obtained from the study of polished ores. He gives short descriptions of a number of copper, silver, and gold deposits, and summarizes the conclusions that may be drawn from them in 48 paragraphs. These conclusions constitute an important contribution to the science of ore deposits.

FABLES, J. C. 'The Precipitation of Copper from the Mine

Waters of the Butte District,' *Bull. Amer. Inst. Min. Eng.*, 79, pp. 1267-1285 (1913).

It is stated that the waters pumped from the mines in the early years of the district contained little copper, and that the metal appeared in the mine waters after the deeper workings were filled with copper-bearing waste.

GRATON, L. C. 'Investigation of Copper Enrichment,' *Eng. & Min. Jour.*, Vol. 96, pp. 886-887.

Scope of the investigations of the 'Secondary Sulphide Commission.'

GRATON and MURDOCK. 'The Sulphide Ores of Copper. Some Results of Microscopic Study,' *Bull. Amer. Inst. Min. Eng.*, 77, pp. 741-786 (1913).

The most important paper that has as yet appeared on the microscopic study of polished sections of copper ores. Photomicrographs show the complex development of successive copper sulphides, and rarely a simple precipitation of chalcocite. The following order is recognized in a number of ores: (1) Secondary chalcopyrite into (2) bornite, into (3) covellite, into (4) chalcocite. Pyrrhotite, however, goes directly into chalcocite without intermediate products. All the copper sulphides observed, occur both as primary and secondary minerals. Criteria suggested (in part provisional) as indicating a primary origin for chalcocite are: (a) primary "intergrowth" of chalcocite and bornite; (b) cleavage. "Sooty chalcocite" is not necessarily secondary, but is the result of the disintegration of the ores near the top of the sulphide zone.

GROUT, F. F. 'On the Behavior of Cold Acid Sulphate Solutions of Copper, Silver, and Gold, with Alkaline Extracts of Metallic Sulphides,' *Econ. Geol.*, Vol. VIII, pp. 407-433 (1913).

Mr. Grout was rather unsuccessful in his attempts to form secondary sulphides from acid solution, of a strength corresponding to analyses of mine waters, and acting on sulphides from which the fine material was sifted out by means of a 200-mesh sieve. When the finest material was used he was more successful, although the action is slow. Whenever much precipitation occurred, the free metals were prominent. He doubts, therefore, if secondary sulphides are formed by the reaction of acid solutions on primary sulphides. He investigated the question whether or not the precipitation is caused by H_2S formed by the attack of H_2SO_4 on pyrrhotite and alabandite, the two minerals that have been proved to develop this gas copiously, under the attack of dilute H_2SO_4 . He showed that pyrrhotite does not evolve H_2S when copper sulphate is added to the solution containing H_2SO_4 , and that the relatively rare alabandite is the only sulphide that precipitates copper "notably" as a sulphide, from an acid solution. Upon treating pyrite with a solution of alkaline carbonates or hydrates, and adding the extract to the acid sulphate solution of copper, he obtained prompt and complete precipitation of the metallic sulphides, and suggests, therefore, the secondary sulphides are formed in nature at a point where the descending acid solutions mingle with deeper alkaline solutions.

GUILLEMAIN, C. 'Zur Kenntnis der Lagerstätten in der Provinz Katanga,' etc. *Zeit. für Prak. Geol.*, XXI, 320-338 (1913).

He shows that the copper contents of the great Katanga mines, Congo Free State, are concentrated by the process of laterization, that is, weathering under tropical conditions, the resulting minerals being oxides and native copper.

KEMP, J. F. 'Influence of Depth on Metalliferous Deposits,' *Min. & Eng. World*, Vol. XXXIX, pp. 394-391 (1913).

Discusses changes with depth caused by downward enrichment as well as those that take place in the primary ores.

KRESCHE, P. 'Primary and Secondary Ores Considered with Especial Reference to the Gel and the Rich Metal Ores,' *Mining and Scientific Press*, Vol. 107, p. 418-423 (1913).

Discusses the rôle of colloidal solutions formed by oxidation.

LINDGREN, WALDEMAR. 'Mineral Deposits,' chapter XXIX, pp. 780-844 (1913).

PALMER and BASTIN. 'Metallic Minerals as Precipitants of Silver and Gold.' *Econ. Geol.*, Vol. VIII, pp. 140-171 (1913).

The majority of the common sulphide minerals are shown to precipitate native silver or a mixture of silver and silver sulphides from neutral and acid solutions of silver sulphate. The chemical equation is established, governing the precipitation of native silver by the mineral niccolite. This throws light on the formation of the rich secondary native silver deposits of Cobalt, Ontario. Other examples showing secondary enrichment by the deposition of native silver are given. For example, in the Up-to-date mine, near Caribou, Boulder county, Colorado, Bastin found secondary chalcocite, bornite, silver, and covellite in a calcite gangue. Pyrite galena and sphalerite are the least active of the common sulphides in precipitating native silver. All the sulphides precipitate native gold.

RANSOME, F. L. 'Note on Nomenclature of Secondary Ores.' *Econ. Geol.*, Vol. VIII, p. 721 (1913).

SALES, RENO. 'Ore Deposits at Butte, Montana.' *Bull. Amer. Inst. Min. Eng.*, 80, pp. 1523-1627. Review, *Mining and Scientific Press*, Vol. 107, pp. 453-459 (1913).

A splendid structural study of the Butte copper deposits. The geological evidence presented to show that the deeper chalcocite was formed by ascending 'primary' solutions seems conclusive. The conclusions as to genesis also seem well founded. The suggestion is an interesting one that there was but one period of mineralization, and that the difference in the mineralogy of the ore deposits in "the central, intermediate, and peripheral zones" are due to changes in the character of the solutions, resulting from the action of these upon the country rock. We need more mineralogical and experimental data on this subject. A satisfactory microscopical and chemical study of the Butte ores and accompanying rock alterations will furnish us the data yet lacking for the understanding of these complex deposits.

SHANNON, EARL V. 'Secondary Enrichment in the Caledonia Mine, Coeur d'Alene, Idaho.' *Econ. Geol.*, Vol. VIII, pp. 565-571 (1913).

Rich cabinet specimens, from this locality, of native silver and tetrahedrite and covellite, are known to mineral collectors. The author discusses these, and shows that they are products of secondary enrichment. He suggests that enrichment has taken place in this mine, and not in most of the other mines of the district, because of the smaller amount of siderite present in the primary ore of the Caledonia mine.

SPENCER, A. C. 'Chalcocite Enrichment.' *Econ. Geol.*, Vol. VIII, pp. 621-652 (1913).

This is one of the most suggestive papers that has appeared on the subject. The chemistry is treated more fully and logically than elsewhere. The author emphasizes for the first time in print, that the formation of the secondary copper sulphides is not simply a precipitate of chalcocite on pyrite or other sulphides, but that the formation runs through a series of products which he suggests is pyrite into chalcopyrite into bornite into covellite into chalcocite. These changes are suggested by changes in colors in his artificial precipitates. In regard to the moot question of the effect of calcite gangue, he shows that secondary copper sulphides are formed in calcite gangue when cupric and ferrous sulphates are present.

THOMPSON, A. P. 'The Relations of Pyrrhotite to Chalcopyrite and Other Sulphides.' *School of Mines Quarterly*, Vol. XXXIV, pp. 385-395 (1913).

From the study of polished sections of pyrrhotitic copper ores, Mr. Thompson finds that the primary sulphides from

the various mines studied show the same order of development, which is: (1) pyrite, (2) blend, (3) pyrrhotite, (4) chalcopyrite. The later sulphides replace both the earlier sulphides and the gangue as well.

TOLMAN, C. F. 'Secondary Sulphide Enrichment.' *Mining and Scientific Press*, Vol. 106, pp. 38-43, 141-145, 178-181.

A general review of the subject. Emphasis is laid on the field study of the subject, and the author discusses the problems presented during the study of the disseminated copper deposits of the southwestern United States.

WELLS, R. G. 'Electro-Chemical Activity Between the Solutions and Ores.' *Econ. Geol.*, Vol. VIII, pp. 571-578 (1913).

Mr. Wells gives a simple method for measuring the current and electromotive force developed by the action of various solutions on sulphides. He concludes that "electro-chemical action is an almost necessary accompaniment of chemical action in the alterations going on in ore deposits," and suggests that there may be natural circuits, formed between different sulphides of the ores and the ore solutions, reduction taking place at one place (the cathode) and oxidation at another place (the anode of the circuit).

WHITMAN, A. R. 'Vadose Synthesis of Pyrite.' *Econ. Geol.*, Vol. VIII, pp. 455-467 (1913). *Mining and Scientific Press*, Vol. 107, p. 928 (1913).

The author designed apparatus to test the successive processes of oxidation, solution, and re-precipitation of pyrite. He succeeded in forming crystalline secondary pyrite, and discovered the importance of kaolin in assisting precipitation. He also proved that the descending acid products of oxidation of pyrite are neutralized, and by further percolation become alkaline.

WINCHELL, H. V. 'Persistence of Ore in Depth.' *Mining and Scientific Press*, Vol. 107, pp. 332-334 (1913).

Discusses the effect of depth especially on secondary processes of ore formation.

Metal Production of Washington in 1913

The total value of the metal mine output of Washington in 1913 was slightly more than \$1,000,000, a decrease of 6% from the value of 1912, according to preliminary estimates of C. N. Gerry, of the U. S. Geological Survey. This was due in part to decreases in silver and copper production and in part to somewhat lower metal prices. An increase of 2% gave a gold output valued at \$694,000. About 78% of the gold output came from crude ore and concentrate shipped, largely the former, and about 22% from cyanide and amalgamation bullion.

There was a decrease in silver yield of about 21% from 413,538 oz. in 1912 to about 326,000 oz. in 1913. The silver output was evenly divided between the silicious ores of Republic and the copper ore of Chewelah. The silver content of the latter decreased.

The copper output decreased about 9%, from 1,086,010 lb. in 1912 to about 986,000 lb. in 1913 as a result of curtailed production from Chewelah district. No zinc ore was shipped from the state, but shipments of lead ore were made from Stevens county, giving an output of nearly 300,000 lb., as against 127,387 lb. in 1912.

The San Francisco mint in 1913 received a total of 2,375,651.75 oz. of gold, valued at \$49,109,079.18, as against 2,522,544.75 oz., worth \$52,145,627.10, in 1912.

The Cerro de Pasco Smelting Plant

By SPENCER BISHOP

The smelter of the Cerro de Pasco company is situated at La Fundicion, Peru, a town having an elevation of 14,000 ft. Because of the altitude, the Company has a great many difficulties to fight against

and deep cañon for 98 miles, Tielio is reached, which is the highest station on the road, being 15,665 ft. above sea-level. A few hundred feet beyond the station the last tunnel is entered, where the elevation is 50 ft. higher than at Tielio. Half way through the tunnel the grade starts down-hill to Oroya, elevation 12,000 ft. above sea-level, which is reached at 5 p.m. and is 130 miles from Lima.

There are three long switch-backs, seventeen bridges, and sixteen tunnels on the road. At Oroya a change of cars is made for the smelter. This new line is owned by the Cerro de Pasco Mining Co., and runs from Oroya to the coal mines at Goyelarisquisga. There are two branches on the road, one of about six miles which runs to Cerro de Pasco, and the other about eleven miles long which runs to the other coal mine at Quishuarcaucha. The smelter at La Fundicion, 75 miles from Oroya, is reached about 9 p.m.; and eight miles beyond the smelter, Cerro de Pasco, where most of the copper mines are situated, is reached by 9:45 o'clock.

Cerro de Pasco boasts of 25,000 inhabitants. It lies at an elevation of 14,600 ft., in a saddle of a mountain range, through which runs an old trail to Lima. The town is over a hundred years old. Various interpretations have been given to the name. At a glance, 'A Pass in the Mountain' appears correct, but inasmuch as *pasco* in the Indian dialect means 'a night's camping place,' more guessing is required for the true meaning. The Indians in the neighborhood seem

which are not seen or thought of by those who have not been there. There is snow, hail, or rain almost every day of the year. The average temperature is 44°F. The great majority of people going to that altitude are afflicted with *soroche* (mountain sickness), and the few who escape it have a great deal to be thankful for. The sickness is like a severe case of sea-sickness accompanied by sharp pains at the base of the brain and in the chest, lasting from two days to two weeks. The attack may occur each time one goes from a low to a high altitude. The fear of pneumonia is always present, as in any high altitude, but nature favors mankind, for germ diseases are not contracted as easily as in lower altitudes.

Callao is the port of entry, and also the terminus of the Peruvian Central railroad. Eight miles inland is Lima, the largest city in Peru. From here the ascent of the mountains commences. Leaving Lima at 7 a.m., the very gradual climb is begun. For an hour the roadbed is on one side of a valley which soon contracts to a ravine, just wide enough for the Rimac river and the roadbed. Now and again it widens so that small towns can find room for their mud huts. At 3 p.m., after winding up the narrow

CONVERTER ROOM.

to be ignorant of the origin of the name.

Great changes have taken place since the smelter was started, and problems have been solved that were at first thought to be impossible. From three 56 by

180-in. blast-furnaces and six 7-ft. Parrot-type converters, the plant has grown until it now consists of five blast-furnaces, two 10 ft. by 25 ft. 10 in. Pierce-Smith basic-lined converters, two 11-ft. spherical con-

verted, with the result that the present battery comprises two 10-ft. by 25 ft. 10-in. Pierce-Smith, two 11-ft. spherical, and two 7-ft. Parrot converters, the last two being used only occasionally. At present a

EXTERIOR OF SMELTER.

verters, and two of the old 7-ft. Parrot-type converters, five 19 by 60-ft. coal-fired reverberatory furnaces, fourteen 18-ft. six-hearth McDougall roasters, and ten Dwight-Lloyd sintering machines.

The blast-furnaces, converters, and new dust chamber have been remodeled. The lower parts of three furnaces have been left unaltered, the old brick tops were replaced by steel similar to those on the two completed furnaces, with the addition of a 9-ft. gooseneck instead of one of 6-ft. diameter. This larger flue proved to be exceptionally satisfactory. From constant use, these furnaces had opened out to 72 in. at the tuyeres, making the furnaces 72 by 180 in., although the two new ones are 48 by 177 in. With a blast of from 32 to 36 oz., these furnaces are smelting about double what they originally did.

The McDougall roasters have been installed as they were needed, there being now fourteen of them. A new flue is being built to increase the draft, so that the capacity will be greater than at present. Two of these furnaces are used to dry silica for the basic converters. The others roast ore for the reverberatories.

Only three of the five reverberatory furnaces are in constant use. Each furnace smelts 60 tons of charge with 45 tons of coal. One of these furnaces has waste-heat boilers attached, and with the three 300-hp. boilers, 400 boiler horse-power is obtained. The steam is piped to the power-house. With the remodeling of the furnaces, more converters were necessary, and the original six Parrot-type were to be replaced by five 11-ft. spherical acid-lined converters. Before these had been installed, a Pierce-Smith basic converter was

generated by means of three Allis-Chalmers units which are being installed. The electricity will be sent to the smelter, 75 miles away, at 50,000 volts. There it will be reduced to 10,000 volts for the mines and 2200 volts for smelter use. At the mines 250 volts will be used for the motors. The system of rope-drive connecting the air-compressors which is

used in the smelter power-house will also be used at the mines. The steam hoists will remain, but will be operated by air in place of steam.

Quite a few foreigners are to be found among the employees, but the lower class of labor is picked from the natives. Unfortunately, these are very ignorant, small in stature, slow of action, superstitious, and not muscular. It takes several of them to do the work that the average white man can do. Most of the natives come from the agricultural districts and

SMELTING PLANT AND STACK.

used in the smelter power-house will also be used at the mines. The steam hoists will remain, but will be operated by air in place of steam.

Quite a few foreigners are to be found among the employees, but the lower class of labor is picked from the natives. Unfortunately, these are very ignorant, small in stature, slow of action, superstitious, and not muscular. It takes several of them to do the work that the average white man can do. Most of the natives come from the agricultural districts and

have no idea of mechanical work. Any excuse to lay off from work is welcomed, and the many religious holidays, together with 'pay-day,' afford the opportunity.

At La Fundicion the Company has a coal-washery, and seventy 12-ft. beehive coke ovens in which they make most of their own coke. In addition to the group of mines at Cerro de Pasco, the Company is operating mines at Morococha, from which large quantities of high-grade ore is mined. Morococha is a few miles from Tielio among very high mountains, and here the most interesting and wonderful geological formations can be seen.

The Company employs about 5000 men. Of this number, 3000 are at the smelter and the other 2000 in the different mines. At each camp a hospital for emergencies is maintained, and there is also a large, well equipped general hospital at Cerro de Pasco. A small fee is charged each employee toward the maintenance of the hospital.

Developments in the Shushana Goldfields

By E. F. WANN

The recent discovery of placer gold on tributaries of the Chisana river, which with the Nebesna river forms the headwaters of the Tanana, has drawn all of the old-time prospectors toward that district. The existence of gold in the country between the White river on the south and east and the headwaters of the Tanana river on the north has been known for several years, but the cost of getting supplies in from the nearest towns has been such as to bar prospecting except in the most desultory manner. However, with the advent of a sufficient number of prospectors to make the matter of supplies an object to the transportation companies and merchants, conditions will be much more satisfactory.

The rocks in the locality of the find are mainly slate and shales, with intrusions of quartz-porphry. A curious feature of the gravel deposits is the occurrence of a great amount of slate and sandstone in alternate layers, varying from one-sixteenth to three or four inches in thickness. In other places, through what appears to be the old glacial channel bearing the auriferous gravel, can be found granite, andesite, and other rocks that are foreign to this immediate locality. The course of the old glacial bed seems to be in an east-west direction, and its width in the vicinity of the discovery from three to four miles.

The discovery party took out close to \$30,000 from the claim known as No. 1 on Little Eldorado creek, where the wash was about three to four feet deep, and the gravel contained as much as \$27 per pan, \$5 to \$10 worth of gold per pan being common. The bed-rock at this place was overlain in places with a yellowish clayey deposit, evidently formed from the decomposed porphyry, which made the saving of the fine gold, if any were present, impracticable with the means

at hand this season. The scarcity of wood and timber for lumber in the immediate vicinity and the shortness of the season hastened the work so that instead of using a man in the dump-box for puddling the clayey matter, it was rushed through, with only two lengths of boxes below the dump-box, presumably with the intention of reworking the tailing later.

From claim No. 2, on Little Eldorado creek, I understand there was produced about \$30 per day for each man shoveling in. No sluicing was done on this creek except on claims No. 1 and 2. The gravel on fraction 3A, on Bonanza creek, from which claim about \$10,000 worth of gold was taken, was found to contain coarse gold. The gravel is shallow, and as this part of the creek is in the cañon, all of the gold there will probably be found to be fairly coarse. Two silver nuggets, one weighing about 4 oz. and the other 1½ oz., were found in the clean-up, together with galena. Pay-gravel has been found up to No. 13 on Bonanza creek. No other sluicing was done on this creek, and the gold was found to be coarse.

Pay-gravel has also been found on the benches to the right and left of the Little Eldorado, and on the benches of Gold Run creek, a tributary of Glacier creek. The following creeks are also known to contain pay-gravel: Glacier, Gold Run, Big Eldorado, Wilson, Johnson, and Alder Gulch. The total area of the gravel deposits along all of these creeks combined is equal to about fifty or sixty square miles. The appearance of the gravel on the benches and the fact that gold can be panned out of the surface leads one to believe that there will be bench-diggings. These diggings lie in the centre of a region of extensive gravel deposits, evidently of glacial origin. The country rock, where it can be seen in place, looks as if it might contain metalliferous veins. In fact, two or three veins containing gold and copper ore have already been found.

The urgent need of a railroad to open up the rich mineral belt extending from Haines Mission to the lower Tanana is every year becoming more apparent.

Ore reserves in the mines operated by the Kyshtim Corporation, controlling the Russian company, the Kyshtim Mining Works Co., are estimated by R. Gilman Brown as follows, in long tons:

| Mine. | Assured ore. | Probable ore | Total. |
|-------------------|--------------|--------------|-----------|
| Koniukhoff | 517,000 | | 517,000 |
| Smirnof | 482,000 | 163,000 | 645,000 |
| Tissoff | 444,000 | 160,000 | 604,000 |
| Amerikansky | 611,000 | 74,000 | 685,000 |
| Total | 2,054,000 | 397,000 | 2,451,000 |

Large tonnages, proved by drilling, show from 2 to 3.6% copper. If the reverberatory furnace is completed next summer, the output of copper in 1914 should be between 9000 and 10,000 tons.

During November the Elmore vacuum plant at the mines of the Sulitjelma company, Norway, produced 1075 tons of copper concentrate.

Long Lake Power Development

By E. P. KENNEDY

*Long lake, which lies about 2 miles from the beach at an elevation of 727 ft., has an area of 3.1 square miles. It is situated near Speel river, between Ketchikan and Skagway, 35 miles southeast of Juneau, Alaska. Water measurements for eight months and an estimate for the remaining four give a yearly run-off of 21,757 million cubic feet, and as the drainage area is taken at 32.4 square miles, the above run-off amounts to 24 ft., or an equalized yearly flow of 689 cu. ft. per second. The initial plant will use 300 sec.-ft., which is equivalent to a run-off of 10.4 ft. over an area of 32.4 square miles.

The power-plant is to be situated near Second lake, 2000 ft. from and 535 ft. below Long lake, and about 1½ miles from the beach. This plant will consist of two units, each of 5000-kw. capacity and each to be direct connected to a water turbine utilizing 300 second-feet.

To be assured of a continuous flow of 300 sec.-ft., the lake will be drawn on by tapping with a tunnel or by a siphon to a depth of 12 ft., and the two spillways from the lake closed, thus raising the lake level 25 ft., giving an available storage of 37 ft. The cost of this power installaton would be:

| | |
|---|-----------|
| Power-house with two 5000-kw. units complete..... | \$250,000 |
| Pipe-lines, two 60-inch with head-gates | 93,594 |
| Closing spillways from lake | 10,000 |
| Tapping lake | 5,000 |
| Contingencies and incidentals | 3,000 |
| Plant for construction | 13,882 |

Total\$375,476
Or a capital cost of \$37.54 per kilowatt or \$27.95 per horse-power.

The cost of operating the above plant would be, per year:

| | |
|---|----------|
| General expense | \$ 6,000 |
| Operating labor | 6,000 |
| Supplies, etc. | 4,000 |
| Total | \$16,000 |
| Operating cost per year per kilowatt..... | \$1.60 |
| Interest and depreciation, 8% on capital cost | 3.00 |
| Cost of kilowatt-year | 4.60 |
| Cost of horsepower-year | 3.43 |

To be assured of a yearly average of 10,000 kw., the generators should be run at 25% above normal capacity for 6 months of the year while there is a large excess of water, and thus provide for unforeseen shut-downs.

The lake area is 3.1 square miles, or 86,423,040 sq. ft., requiring 20 ft. in depth at this area to provide for the required storage.

This storage is obtained by raising the lake level 25 ft. and drawing on the lake 12 ft. The increased area obtained by raising the lake will make up for the decreased area by drawing the lake and also provide suf-

ficient storage below the 2 ft. of ice.
From flow measurements the following figures are obtained:

| | Measured flow. | Required flow for 300 sec.-ft. | From storage. |
|-----------------|----------------|-----------------------------------|---------------|
| January | 324,187,200 | 803,520,000 | 479,332,800 |
| February | 283,046,400 | 725,760,000 | 442,713,600 |
| March | 374,976,000 | 803,520,000 | 424,544,000 |
| April | 352,512,000 | 777,600,000 | 425,988,000 |
| May | 1,154,390,400 | 803,520,000 | |
| June | 2,947,104,000 | 777,600,000 | |
| July | 5,340,729,600 | 803,520,000 | |
| August | 4,860,492,480 | 803,520,000 | |
| September | 4,473,792,000 | 777,600,000 | |
| October | 803,520,000 | 803,520,000 | |
| November | 518,400,000 | 777,600,000 | 259,200,000 |
| December | 324,187,200 | 803,520,000 | 479,331,800 |

Total666,530
Velocity when carrying 300 sec.-ft., 8 ft. per second:
loss per 100 ft., 0.225. Weight of two lines, 1,337,060
lb.; and estimated cost erected is 7c. per pound.

The steel of which the above pipe is made will have an ultimate tensile strength of 60,000 lb. per square inch. Thickness of pipe is figured from the formula:

$$\text{Diam. in inches} \times \text{pounds pressure} \\ 2 \times 10,000$$

which takes care of the efficiency of joints and allows a sufficient factor of safety. The weight of above pipe is obtained from the formula: weight in pounds per foot (12.5 times diameter in inches times thickness in inches) plus 10 lb. This weight takes care of laps, rivets, asphaltum, and paint.

The Slater Leaching Process for Copper Ores

By H. W. MORSE

Among the new processes for the extraction of copper from its ores in the wet way, there is one of much interest, chemically as well as technically. This is the cyclic hypochlorous acid process of H. B. Slater, of Riverside, California. The chemical reactions involved are simple enough fundamentally, but they are sufficiently unusual to be worth careful consideration and some study. Inasmuch as the process is a cyclic one, it will perhaps be best to describe the operations and reactions in a series of steps. The completeness of the cycle can then be checked from point to point of the process.

The Leaching Liquor

The leaching liquor comes from the anode compartment of an electrolytic cell of ordinary type. A 15% solution of common salt is used here, and in it there is suspended ferric hydroxide (produced at the third step), the quantity used depending on the copper content of the ore to be treated. Electrolyzing, the reaction is:

half of the chlorine going to form ferric chloride and half to form hypochlorous acid. Electrolysis is continued until only a small amount of suspended hydroxide is left. This means that there is but very little free chlorine in the solution; and it means, in practice, that very little chlorine escapes into the air. For an ore containing 2 to 2.5% copper, the lixiviant will contain 5 to 7 gm. per litre of iron as ferric chloride, and a corresponding amount of hypochlorous acid. In the cathode compartment there is formed during electrolysis sodium hydroxide, in amount equivalent to the quantity of chlorine produced. This is used at a later stage of the process.

Ore ground to 40 mesh is easily treated. If chalcocite be assumed to be the chief copper mineral present, the leaching reaction, as far as the hypochlorous acid is concerned, is:

as a part of the sulphur is freed in elementary form. The SO_2 produced in this reaction reduces part of the cupric chloride to cuprous chloride:

so that even at this point in the process a considerable portion of the extracted copper is present as cuprous chloride, held in solution in the sodium chloride solution.

At this point the leaching liquor contains ferric chloride, ferrous chloride, cupric chloride, and cuprous chloride, all in salt solution. To it there is added sufficient of the sodium hydroxide solution, from the

cathode compartment of the cell, to completely precipitate all of the iron as hydroxide, according to the reactions:

This last reaction is an interesting one chemically, especially because cupric chloride acts here as an oxidizing agent, raising ferrous to ferre iron. This reversal of the usual order of things takes place because of the complete and immediate removal of the ferric iron as hydroxide as fast as oxidation takes place. A slight excess of the sodium hydroxide causes no precipitation of copper as hydroxide, for the copper is all locked up in the complex (perfectly colorless) form with the sodium chloride, and the concentration of ferrous iron is so slight that a considerable excess of hydroxide is required to produce a precipitate.

The combined reduction effect of the ferrous chloride at this stage and the sulphur dioxide in the previous one results in the complete reduction of all the copper to the cuprous form. This is of practical importance, since it is only necessary to supply a single equivalent of chlorine for each copper molecule instead of two equivalents, which would be needed if the copper were to be extracted as cupric chloride. As a matter of fact, it is in practice only necessary to supply a very slight excess of chlorine in the leach over that calculated for the cuprous chloride equivalent.

Recovery of Copper

The copper can, of course, be recovered by the usual methods, or it can be precipitated with the aid of the sodium hydroxide as cuprous hydroxide. If this precipitation is made with hot sodium hydroxide solution, air oxidation is rapid and the ordinary black oxide of copper is formed. Probably the reaction: $2\text{CuOH} + \text{O} = 2\text{CuO} + \text{H}_2\text{O}$ will express this step. The black oxide so formed might well be cast into blocks and used as cathodes in the electrolytic cell giving metallic copper, and resulting in a noticeable decrease in the working voltage of the cell.

It is evident that the process is completely cyclic chemically. No chemicals are brought in from outside except the salt, which may be lost in the final wash waters, and this can be reduced to as low a point as may be desirable in practical operation.

The following points are worthy of special consideration: (1) Ores of low total sulphur content can be treated. (2) The ore need not be roasted. The only reason for roasting any part of the ore treated would be to bring up the iron content of the leach in order to produce sufficient ferric hydroxide to restore the original concentration for the next leach.

This might be necessary in the case of an ore containing much lime. (3) If the ore is not roasted, practically none of its iron is leached out with the copper. (4) The separation of the iron from the copper is easy and complete. (5) All materials used are produced in a single operation in a single electrolytic cell, except the salt lost in the final wash waters. (6) The sodium hydroxide produced in the cathode compartment is completely utilized in separating the iron from the copper and in the subsequent precepitation of the copper. (7) The precipitated ferric hydroxide separated in (6) is used in the preparation of the succeeding lixiviant. (8) Extraction is very rapid and complete. With agitation, using a 40-mesh ore, 95% extraction can be had in four to six hours. (9) Copper produced by this process is extremely pure. None of the other metals can follow it into its complex salt with sodium chloride, and they are almost completely removed with the iron by precipitation as hydroxides. For the 'porphyry ores', so called, and for non-roasting ores in general, the Slater process appears to combine nearly the maximum number of advantageous features with but very few objectionable ones.

The Ethics of Mine Promotion

By J. PARKE CHANNING

*I presume that a great deal of misconception regarding mines is a relic of forty or fifty years ago, when mining was not an industry, but was an adventure. The West was unprospected, and when rich ore was discovered, the cost of converting it into cash was relatively low as compared with the product, or, in fact, was negligible. A mining scheme was something like the quest for buried treasure, where success depended not upon the cost of the adventure, but upon the luck which one had. The successful ventures were dangled in front of the eyes of business and professional men by those unscrupulous individuals who cared nothing for the investor.

In the meantime, mining has become a recognized industry in which the highest technical skill is employed in prospecting for orebodies, in developing them, and in finally equipping and operating them. But the memory of the unscrupulous promoter still lingers in the mind of the investor, and he therefore confounds their operations with those of people who make mining a business.

Probably few people realize today that the United States Steel Corporation is primarily a mining company, its main assets being its holdings of favorably situated iron ore and coking coal lands. The same thing applies to the larger copper-mining companies, and to many of the gold properties, such, for example, as those on the Rand, or in southern Alaska.

In modern mining the first and primary desideratum

is to get a large body of ore. The question of grade and the cost of working it determines its ultimate value. As I have frequently pointed out, there are really only two primary sources of wealth in the world, mining and agriculture, and mining is just as important as agriculture. While the same methods of analysis may be applied in determining the value of a mining company as in arriving at the value of a railroad, still there is one factor in mining which gives an added value, and that is, the continued chance of finding either new or richer ore upon a property which is being exploited. This chance is one which induces the shrewd investor to go in for mining. Care should be taken, however, by the investor to discriminate between the searching for and developing of new properties, and the exploitation of those which have been found and are already worked or about to be worked. The searching for new mines is a more or less hazardous business. One may take ten different prospects, spend money in developing them, and be extremely fortunate if one of them turns out to be a mine. To do this kind of work requires a large capital so that the risk may be reduced, and in America we have such companies as the Guggenheim Exploration, the General Development Co., and the United States Smelting, Refining & Mining Co., that do this kind of work. If they take up a property which turns out badly, the expense is charged to profit and loss, and they trust that later on some successful development may recoup them for the loss sustained in the nine, nineteen, or ninety-nine failures.

It is said that the success of a few St. Louis business men in unexpectedly developing a large mine in Montana a number of years ago has induced so many people from that city to go into the development of prospects that the sum total of expenditures for this class of work has been far greater than the dividends poured into that city from the original successful mine. On the other hand, those investors who have gone into the porphyry copper mines, either in their early days or when the price of copper was low, have reaped a most satisfactory reward. The tendency nowadays is for good mining companies to give annually not only figures of cost and production, but estimates of actual ore developed, and also the opinion of its managers as to its future prospects. With all these data available, the investor has an opportunity of making up his own mind as to the risks of profit or loss which he takes by buying any mining stock. For many years the principal transactions on the Boston Stock Exchange have been in mining shares, and within the last few years the shares of the better copper companies are dealt in upon the New York Stock Exchange. The investor should be careful to invest in shares which are dealt in either on some well known exchange or on the Curb. Unfortunately, there are many so-called mining stocks which are very easy to buy, but extremely difficult to sell at any price.

*Abstract from *The Annalist*.

Gold Dredging Abroad in 1913

By CHARLES JANIN

Yukon Territory

During the year interesting details regarding the operations of the Yukon Gold Co. at Dawson and Iditarod, the latter being in Alaska, were made public. They were printed in the report by O. B. Perry which

for the first few weeks after the dredge reached the tested area were in excess of the average value of the whole area shown from prospecting results. Information given to shareholders shows the total from the 'tested area' to date as follows:

DREDGING GROUND ON THE PARACALE RIVER.

appeared in the *Mining and Scientific Press* on June 28 and need not be repeated. The following summary will serve to indicate the extent and cost of the work:

| | Production cu. yd. | Production c. per yd. | Costs c. per yd. | Operating gain. |
|-----------------------|-----------------------|--------------------------|---------------------|----------------------|
| Dawson dredges ... | 5,157,280 | 64.88 | 39.64 | \$1,765,736.97 |
| Iditarod dredges .. | 172,333 | 2.34 | 45.91 | 324,926.09 |
| Hydrauliclicking | 2,967,750 | 21.22 | 9.37 | 351,090.53 |
| Miscellaneous | | | | 279,665.56 |
| | | | | <hr/> \$2,721,419.15 |

From the operating profit as shown was deducted, royalties \$692,995.43; amortization and deferred charges, \$577,146.27; interest, general expense, and examinations, \$378,685.88, making a total of \$1,648,827.58.

Colombia

Considerable interest has been manifested in the dredging operations of the Pato dredge, and a boom in the shares followed the announcement that recoveries

| | Cu. yd. | Estimated recovery. |
|------------------|---------------|------------------------|
| To Oct. 21 | 239,492 | \$140,617.02 |
| To Oct. 28 | 24,100 | 15,900.00 |
| To Nov. 4 | 26,370 | 17,500.00 |
| To Nov. 11 | 25,250 | 21,250.00 |
| | <hr/> 315,212 | <hr/> \$205,267.02 |

These values represent an average of 65c. per cu. yd., and for the last week \$1.23 per cu. yd., which are certainly most encouraging. Previous to reaching the tested area the dredge dug approximately 473,500 cu. yd. with a recovery of \$80,380, and the recovery for the week ending July 15 was only 3.5c. per cu. yd. The low values caused disappointment and scepticism among the shareholders, who began to weary of the stereotyped phrase "when the dredge reaches the tested area." When, however, the high weekly returns from the dredge were announced, a reaction took place, and some little trading was done in shares. The estimated profits

from the Pato are shown from the following extract from the report by Theodore Hoover: "The Pato has not been operating for a sufficient length of time to enable us to make any alteration or correction in the engineer's original estimates. We can, therefore, only introduce into our calculations the estimates which we made some years ago, and hope that these will be borne out in actual results. These estimates were to the effect that the Company had 310 acres of available dredging ground at Pato which would yield a net profit of £350,000. They estimated that this would be returned at the rate of £50,000 per annum, which indicates a life of seven years."

An investigation is being made at the present time of other parts of the Pato property, including ground on California Hill, which it is expected can be profitably worked by hydraulicking.

The Certigue Dredging Co. operated a dredge on the Certigue river for a short time during 1912, but the dredge sank in December. The operations were in the nature of a test during an examination of the property. The dredge which had been built some time required considerable work to put in order and many delays were caused by repeated repairs to the dredge and over fuel and boiler troubles. The dredge worked intermittently from August 17 to November 11, but was operated at full capacity for 239 hours only. During the test the dredge handled 22,700 cu. yd. of gravel. The total recovery of gold and platinum was a little over \$7000, and it was assumed under proper conditions the operating costs should not exceed 10c. per cu. yd. It was expected that a new dredge would be put on this property. Below the Pato ground is the Pochet property on which a 5-ft. Werf Conrad steam dredge has been working some years. The dredge is open-connected type, has a steel hull, and digs to a depth of 26 ft. below water level and during high water cannot reach bedrock. While the yardage handled is small, and the dredge works only one shift, the amount recovered per yard is good, and the dredge has been a profitable venture to the owner. His familiarity and consequent success with native labor permits a lower operating cost than if it was necessary to have an expensive European crew which, under the same conditions, would require closing the dredge down. A new dredge to be built in 1914 is that of the American Goldfields Development Co., which has been doing considerable prospecting to the south of the San Juan river, and will build a dredge to recover the platinum found in some of the ground prospected. Several prospecting parties have been sent to Colombia by different concerns during the year, and now that the success of the Pato dredge is assured, no doubt other investigations will follow. South America is one of the few fields for dredging possibilities that has not yet been exhaustively investigated.

British Guiana

The Guiana Gold Dredging Co. operates four dredges on the Potaro river. It is one of the most profitable

mining enterprises in Guiana. The production from the dredges has shown a steady increase yearly since the Company began operations in 1907. The following table showing production by years and dividends paid is of interest:

| Year. | Crude oz. of gold recovered. | Dividend paid. |
|---------------|---------------------------------|-------------------|
| 1907-8 | 2955 | 12½ |
| 1908-9 | 3737 | 10 |
| 1909-10 | 4455 | 10 |
| 1910-11 | 5885 | 10 |
| 1911-12 | 7511 | 10 |
| 1912-13 | 9160 | 10 |

The gold recovered for the year ending March 31, 1913, was \$174,570.40. Expenses were:

| | |
|--|--------------|
| Management and operation | \$88,535.16 |
| Prospecting | 4,085.00 |
| Royalty on gold shipped | 6,889.10 |
| | <hr/> |
| | \$ 99,509.26 |
| London and agency expenses depreciation of dredges written off on claims, etc. | 33,050.58 |
| | <hr/> |
| Total | \$132,559.84 |

Yardage figures are not given and are probably not kept as the operation of the dredges extends over about twenty miles of river and any figures of yardage would only be an approximation at best. With the exception of an accident which stopped the work of one dredge for two months, the four dredges of the Company worked steadily throughout the year.

The Minnehaha Dredging Co. operating on the same river produced 2472 oz. of gold. The Company prospected some new areas and expects to build a new dredge in 1914.

Philippine Islands

In the Paracale district, Ambos Camarines, according to the Manila correspondent of the *Press*, there are five dredges at work as follows: (1) the old Risdon dredge on the Malaguit river; (2) the old Stanley, or Maximilo, dredge on the headwaters of the Paracale river; (3) two dredges belonging to the Paracale Bucket Proprietary in the lower part of the river; and (4) the New York Engineering Co. dredge on the Gumaos river. One of the new dredges intended for operation on the Paracale river sank last May. The machinery is being recovered, but it will have to have a new pontoon. The steel hull and machinery for the new dredge on the Umirai river has arrived in sections from Australia and is being set up.

The Yuba Construction Co. has been building a dredge on the Malaguit river which was to be completed in November. This boat is equipped with 5-ft. buckets and will have a modern hull.

Considerable interest has been manifested in the work of the Gumaos dredge, which was built in 1912 and which is the first American dredge of modern type to be put in operation in the Islands. The running time has not been so high as expected, but is fair, considering the sunken timber encountered, and that the boat is operated with a Philippine crew. In February,

1913, the dredge dug 57,000 cu. yd. in 436 hours running time, and recovery averaged 31.7c. per yard. The time lost during the month was due to the necessity for turning the dredge at the end of a narrow gorge. During March 42,000 cu. yd. averaging 64c. was handled in 320 hours, the dredge being shut down for 12 days waiting for a new stacker belt. In April 130,000 cu. yd. was handled averaging 15c., and for May 105,000 yd. in about 500 hours running time. This would total 304,000 yd. in four months. While the actual operating expenses are not available at this writing, and over such a short period would virtually be nothing more than an indication for future estimations, it may be of some interest to mention the fuel and labor costs. Fuel runs about \$2000 per month; native labor \$1700, and white labor, including dredge-master \$1750; so, for labor and fuel, the total is \$5450 or \$2725 per month. The dredge is a 5½-cu. ft. steam dredge, with a wooden hull and was built at a cost of \$150,000. The life of the property was estimated at five years. The dredge was built by the New York Engineering Co., and it was designed to dig 38 ft. only, but has repeatedly dug to a depth of 45 ft., and a 25-ft. extension has been put on the ladder to dig deeper ground during 1914. This extension is necessary to reach the deeper pay ground as recoveries have fallen from 2000 oz. to 220 per month.

Mining Costs in the Coeur d'Alene District

Detailed mining costs at the Snow-Storm mine are presented in the following table. The ore is mined, through adits, from a vein dipping at an angle of 65°. The method employed is a combination square-set and fill.

| | | |
|--|------------------------------|-----------------------------|
| | 48,897 tons shipping ore. | 50,648 tons milling ore. |
| Foremen, bosses, machinists, nippers, and supply men..... | \$0.151 | \$0.160 |
| Timbermen and carpenters..... | 0.216 | 0.199 |
| Miners | 0.192 | 0.221 |
| Carmen | 0.130 | 0.132 |
| Shovelers and laborers..... | 0.340 | 0.348 |
| Power labor | 0.025 | 0.023 |
| Hoist engineers | 0.017 | 0.017 |
| Total pay-roll expense | \$1.071 | \$1.100 |
| Explosives | 0.070 | 0.067 |
| Illuminants | 0.015 | 0.015 |
| Iron and steel | 0.010 | 0.011 |
| Miscellaneous supplies | 0.046 | 0.047 |
| Timber and lagging | 0.199 | 0.179 |
| Power supplies | 0.002 | 0.002 |
| Electric power | 0.022 | 0.044 |
| Wood and coal | 0.002 | 0.003 |
| Stable and stock | 0.007 | 0.006 |
| Total supplies | \$0.373 | \$0.374 |
| Total cost per ton | \$1.444 | \$1.474 |

Cloths on an Oliver filter at the Black Oak mine, Soulsbyville, California, were recently removed after 17 months' work.

Gravel Mining in Alaska and Siberia

The following is from the report of the annual meeting of the Lena Goldfields, Ltd., held in London on December 16, 1913. This Company controls the Lenskoie properties, and C. W. Purington has recently examined them. In his preliminary observations, Mr. Purington refers to one important item, namely, the actual costs which he can certify on the west coast of America in relation to the actual conditions which prevail on the Lenskoie. He points out that on the permanently frozen benches at Bonanza creek, in the Klondike, about 3,000,000 cu. yd. of gravel that was thawed was handled at a working cost of 9.37c. per cubic yard, and he estimated that the future operations of that Company will not exceed 10c. per cubic yard. He states that he does not see any reason why Lenskoie operations on a large scale should cost any more, and with the exception of the more rounded character of the gravel, the Klondike conditions are more difficult than the conditions on the Lenskoie for the following reasons: (1) the water-supply is not so abundant; (2) the price of labor and supplies is higher; (3) the expense of building ditches is greater than in the Lena, and the conditions for obtaining the necessary head are not so good; and (4) the permanent frost is not of so continuous or widely distributed a character in the Lena district as it is at Nome or in the Klondike. On the other hand, the season would probably be shorter, not exceeding 120 days. Therefore, on the tested Lenskoie ground there is from five to seven years' life, there are economies which can be and ought to be introduced, there is still, according to the Lenskoie report, a great length of the Bodaibo stream to be tested, there are hydraulicking possibilities, and there are legitimate profits to be made from the trade which the very considerable population on the mines stimulates.

The dewatering problem at the Washoe plant, Anaconda, consists of reducing 20,000,000 gal. of pulp with 2% down to about 12% solids. This is finer than 200 mesh and nearly all colloidal. Tests showed that a Dorr continuous thickener 28 ft. diameter and 3 ft. deep has approximately 85% of the capacity of a tank 28 ft. diameter and 10 ft. deep, so a series of Dorr thickeners is being installed. The overflow from them will pass to 20-deck buddles. The concentrate from the latter goes to five 50-ft. diameter by 12-ft. deep Dorr continuous thickeners, where it is distributed, and then to Oliver filters for final removal of moisture.

The development of the mining industry in Colombia is indicated by the increase in the exports of gold, which have been as follows in recent years: 1905, \$1,616,936; 1906, \$2,705,465; 1907, \$2,877,742; 1908, \$3,836,875; 1909, \$2,988,711; 1910, \$3,369,954; 1911, \$3,751,833; and 1912, \$6,634,914. *Daily Consular Report.*

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Ore in Sight

The Editor:

Sir—Is the old reliable standard of 'ore in sight' when three sides are accessible really trustworthy? In the Harqua Hala mine in Arizona one block had the three visible faces in rich ore and a 'horse,' entirely concealed, occupied everything but the faces. I ran across another case recently in Mexico. Two eminent American mining engineers made a most careful survey of 26 'visible' blocks of ore and practically certified that there was a profit in sight of over \$1,300,000 U. S. currency. The metal content of over half of it has been extracted at less than the estimated cost per ton, with an extraction higher than the estimate, yet the net profit to date has been little less than \$55,000, or a little over 8% of the certified profits. Are mine buyers justified in paying big fees for such guesses, and can't we devise some better way to guess?

CASSIUS E. GILLETTE.

Washington, December 16, 1913.

The Use of Powder Underground

The Editor:

Sir—While so much is being published about 'Safety First,' would it not be well to take some notice of the dangerous and wasteful use of powder in mines? My own experience has taught me that this is a source of danger that is not always properly considered. I will cite one instance that, while it may seem extreme to most of those who may read this, is not so unusual or extreme as it may appear at first reading. The instance referred to was the use of 165 sticks of 40% powder in a 70-ft. drill-hole. One hundred and sixty-five sticks of powder 8 in. long, placed end to end, will make a total length of 111 ft. Now when 111 feet of 1½-in. powder is compressed into 70 linear feet the diameter will be 1.414 in. Some of the holes were loaded to the collar, and the primers were placed at about the centre of the load. The fuses were cut to have the holes go in the proper order. Now suppose hole No. 6 goes at the proper time and is duly counted, but, unknown to the miner who is counting the shots, it blows two feet of the collar from No. 8, without disturbing the primer. Although there may be no missed shots, yet we have more or less powder that has not been exploded scattered through the rock pile. If this is hard rock, which in this particular case it was, this powder is very dangerous to the shovelers.

In my own experience I have found at least three-fourths of the holes are overloaded, and this applies to soft as well as hard rock. A hole in ordinary rock should not be loaded over half full of powder. In very hard rock the load may be increased to fill two-thirds of the hole, but never more. If this load will not give good results, then increase the strength of the powder, or do better drilling. Miners are apt to increase the load of powder if they have a round of holes that fails to break as they think it should. It is seldom that the miner cuts down the load unless he is compelled to do so by the management or is paying for the powder himself.

R. NOBLETT.

Ray, Arizona, December 16, 1913.

Ore

The Editor:

Sir—I notice with pleasure that Mr. Herzig, in your issue of September 13, 1913, elects to break a lance with T. A. Rickard in regard to the latter's definition of 'ore,' and, if I may be allowed to comment on the engagement, I shall say that the honors are easily with Mr. Herzig. I have always found much that was admirable in the writings of Mr. Rickard, and I have a great respect for his command of the English language, but I submit that his definition of 'ore,' and his defence of it as set out in his answer of the date just quoted, are distinctly lame. It seems to me that Mr. Rickard, in a matter like this, pays the penalty of his undoubtedly high qualifications as a writer of English, in that any lapse is likely to be immediately evident to his readers, and I feel sure he will understand the spirit that prompts me to supplement Mr. Herzig's criticism.

I am, let us suppose, an artist in oils. I paint a picture, putting into it my best endeavors; the result, I know, is not perfect, but it is a sincere attempt at perfection. An art critic appears, and while admitting my recognized ability and talent, proceeds to point out various defects in my work. Now, if I reply, I may do so in several ways. Let us take two of them. Meeting criticism half-way, I may admit my mistakes, and determine to avoid them in the future. Or, I may arise in my wrath and say, "Go and paint a better picture yourself, and then hear my candid opinion of it."

I think it is obvious that the latter is an answer that will satisfy no one, but it is precisely such an answer that Mr. Rickard gives Mr. Herzig. "I challenge Mr. Herzig to proffer a definition of 'ore'; if he will, I can promise to make it look sheepish."

I can almost hear a murmur:

"I am monarch of all I define,

My rights there are few to gainsay:

Ex cathedra I claim that a mine

Is a hole yielding ore that will pay."

As to the promise, I can well admit the possibility of its fulfilment, after examining Mr. Rickard's defini-

tions, and noting how ridiculous he himself makes them appear. Referring to his lecture, 'The Valuation of Mines,' published in the *Mining and Scientific Press*, May 24, 1913, page 766, I should like to quote verbatim two or three sentences, in order to explain my point. The italics are mine.

"*Ore is rock containing sufficient metal to be exploited at a profit. When rock cannot be profitably mined, it is waste.*"

Referring to the cost of mining, "10-dwt. *gold ore* in one locality means *loss*; in another, 5-dwt. *ore* ensures a handsome *profit*. Therefore a definition is required. *Ore* is metal-bearing *rock*, which, at a given time and place, can be mined *at a profit*. *Ore* that is *unprofitable* today may yield dividends at a later period * * * *ore* previously *profitable* becoming *unprofitable* * * *."

Any attempt to insert here the defined equivalent of ore will result, not only in redundancy, but in contradiction of terms.

Mr. Rickard says it is permissible to be redundant in the effort to be explicit. He will hardly go as far as to claim that it is necessary to be contradictory also. In any case, there is surely a weak spot in a definition that requires redundant explanations.

Again, Mr. Rickard trips similarly over his definition of a mine. If a mine is a certain type of hole or excavation, namely, one that yields profitable ore, an 'unprofitable mine' is a contradiction of terms; it is difficult to see what purpose is served by making a definition that involves redundant and contradictory qualifications.

A point to which Mr. Herzig does not refer, is the use of 'which' in the definition of 'ore' quoted above. As the sentence stands, with the comma after rock, 'which' is used in a relative, not a defining, sense, so that we could recast the line thus, "Ore is metal-bearing rock, *and*, at a given time and place, *it* can be mined at a profit." This is obviously not the meaning originally intended by the author, and his definition therefore should be written, "Ore is metal-bearing rock that can, at a given time and place, be mined at a profit."

The defining relative 'that' is of such assistance in just such sentences as this, that it should not be ousted by an ambiguous 'which.'

Even were 'which' retained, the comma after 'rock' is an error. In the following, " * * * to distinguish a mine from a hole in the ground which is fit for * * *" (Mr. Rickard's reply to Mr. Herzig), I think the defining 'that' would have been preferable to 'which.' And I wonder why Mr. Rickard spells 'to-day' without a hyphen.

Finally, shall I submit my definition of 'ore'? And be butchered to make a Roman holiday?

No, sir, it's far easier to be a spectator, though not a silent one, and—it's certainly safer!

G. AUBREY GOW.

Lebong Soelit, Benkoelen, Sumatra, Nov. 13, 1913.

Professional Ethics

The Editor:

Sir—In your issue of December 20, Mr. Hills comes at the 'professional ethics' question from one of its many angles, and his query as to "the right to sell information to another where the first employer has hopelessly failed to pay his bill" certainly raises a point, the fineness of which depends upon the conditions associated with each particular case; this consideration remains unchanged even where an advance payment has been made.

Considering Mr. Hills' experience as a fair example one might presume that, in the vernacular, he got 'stung.' Many reports have been rendered by a large number of engineers for which no compensation was ever received. In this particular case the examination was made at the request of a client existing as a partnership of three men, all interested in the purpose of the examination and equally involved in paying the engineer. The fact that one-third of the fee was paid and the balance not only not guaranteed but even refused, certainly does not justify one of the three partners in withholding permission to the engineer to use the information. Obviously if the partners fulfilled their obligation the information becomes their property, but when they refuse to do this it is reasonable to assume that they should forfeit their rights to the exclusive use of the report. It is also possible that one-third of the fee did not cover expenses; wherein might arise a point for the consideration of equity versus ethics. It appears to me that the logical conclusion in this case, and in others of a similar nature, should be determined by a sense of what is just to client and engineer, and under the circumstances Mr. Hills would be justified in giving his information to the second party.

Ethics always has been and probably will continue to be a mooted question. No set rules can be laid down to govern fine points except that of applying good old common sense. A professional man is usually endowed with ordinary intelligence, and his conception of what is just and right will govern his actions to accord with the dictates of his conscience. If all doubtful questions were looked at from an unbiased viewpoint and judged according to common sense ideas there would be less need for rules on ethics.

J. M. LILLIGREN.

Buckhorn, Nevada, December 30, 1913.

In Venezuela an extensive oilfield is being proved by the Shell and Standard Oil companies, which have acquired extensive interests on the Sea of Maracaibo. The Guggenheims have a large staff of engineers examining the district, and Mr. Reynolds, late of the Anglo-Persian Oil Co., is drilling on behalf of an English and Venezuelan oil company with, it is reported, excellent results. The field is considered of great importance for European markets, as it will have no need of the Panama canal.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Blasting ore by electricity has given results at least equal to those obtained with ordinary safety fuse, according to W. Cullen, I. Donaldson, and W. Waters, whose experience covers over four years on the Rand.

Rolling and otherwise working aluminum reduces its density, this being due to a transformation from a crystalline to amorphous state, according to F. J. Brislee in a paper presented to the Faraday Society. The worked metal was more prone to corrosion because it was amorphous.

A furnace lining of a refractory nature may be made from asbestos and water-glass, according to a writer in the *Brass World*. It is useful for patching or plugging cracks, as it does not crumble as readily as other similar composition made from clay. The materials used are fine asbestos, 40 lb., and water-glass, 60 lb. The water-glass is the sodium silicate of commerce, which is soluble in water. The asbestos and water-glass are mixed to a paste with water so that it can be worked.

At the present time there are 53 alloys of aluminum and copper manufactured. The most important contains about 92% aluminum and 8% copper. This particular alloy has a tensile strength of 20,000 lb. per square inch, but shrinks badly in casting. It has been found that the addition of 8 to 10% of cobalt and 1% of tungsten or molybdenum to pure aluminum or copper-aluminum alloys, yields a metal which casts better and is more readily worked and finished and more non-corrosive than the alloys formerly used.

The corrosion of the iron retorts used in distilling crude petroleum is found to be due to the presence of free hydrochloric acid in the aqueous portion of the distillate, according to E. Pyhälä. The quantity of the acid was 0.107, 0.043, and 0.026% in samples of oil containing 29, 12, and 7% of water, respectively. Water, separated from the crude oil, and having a specific gravity of 1.1426 at 20°C., yielded 0.33% of hydrochloric acid when distilled. The acid was not formed until 86% of the water was distilled over, the temperature then being 125 to 130°C. The acid is probably formed by the decomposition of the chlorides held in solution in the water.

The difficulties in the treatment of the manganiferous ores of El Favor mines of Jalisco, Mexico, while not yet entirely overcome, have been greatly improved, and definite progress has been made whereby a process has been devised which yields 75% of the

silver as against 50% by cyanidation. Definite improvement on the 75% extraction is now practically assured, and as soon as political conditions will permit, steps will be taken to make these changes, as El Favor now has the complete use of its entire milling equipment. There is over a year's supply of ore broken down in the stopes, ready for milling, and all costs of this mining are paid for.

Costs at the Kalgurli mine, Kalgoorlie, during the past fiscal year, when 128,415 tons of ore was treated, were as follows:

| Mining: | Cost per ton. | Milling: | Cost per ton. |
|-----------------------|---------------|--------------------------|---------------|
| Superintendence | \$0.04 | Superintendence | \$0.07 |
| Breaking ore | 0.56 | Rock-crusher | 0.07 |
| Timbering stopes..... | 0.06 | Aërial tramway | 0.07 |
| Tramming | 0.36 | Ball-mills and conveyor | 0.46 |

| Total mining | \$1.85 | Total milling | \$2.82 |

Dredges, as a rule, float in a pond surrounded on three sides by high gravel banks, and on the fourth or back side by irregular tailing piles. It is, therefore, difficult to get the heavy spares on the boats. This is done in some cases by bringing the boats close to the banks, or by lowering the parts needed on to

GEAR FOR LIFTING SPARES ON DREDGES.

a punt or flat-bottom barge floating in the pond. The accompanying illustration shows a device used on the Ophir dredge at Oroville. It simply consists of an I-beam suspended from the bow gantry, and well over the ground being attacked. A crawl works on the beam, and buckets or other spares required are easily placed on the dredge.

Special Correspondence

PORCUPINE, ONTARIO

MILL WORK AT THE DOME.—DOME LAKE, PORCUPINE CROWN, PEARL LAKE.—NORTHERN ONTARIO AND CALIFORNIA EXPLORATION COMPANIES.—KIRKLAND LAKE 'PROPRIETARY.'

Milling results at the Dome mine continue to be satisfactory, and the monthly production has shown a steady increase. The production for November, which was the highest monthly tonnage yet attained in the Porcupine district, totaled 13,820 tons, an increase of 3957 tons in six months. An additional 40 stamps are being installed, and when this is completed the treatment process, which at the present time is an all-slime treatment, will be somewhat changed. The product of the tube-mills will be classified into sand and slime, the former being leached, and a part of the slime will be treated with the present equipment. Eventually the slime may be cyanided direct in filter-presses. It is expected that the addition to the mill will be in operation next May. This plant has been designed and erected by the Merrill Metallurgical Company.

The Dome Lake property is now being operated under the control of the Hudson Bay Mines Co., of Cobalt. It has been decided to sink the shaft to a depth of 400 ft., where it is hoped that the ore-shoots will be longer and more persistent.

The annual meeting of the shareholders of the Porcupine Crown will be held in Montreal on January 28. It is stated that the engineers report will show approximately 50,000 tons of proved ore which averages \$40 per ton. The mill, which has a capacity of 180 tons per day, is operating on the Dorr continuous cyanide system. This is something new for Porcupine, and the management states that excellent results are being obtained. It is expected that at this meeting the directors will commence dividend payments by the declaration of a 3% quarterly dividend.

A special shareholders' meeting of the Pearl Lake Mining Co. will be called in the near future, in order that the report of the general manager, Mr. Fisher, may be presented, and plans for the reorganization of the Company submitted. It is understood that Mr. Fisher's report will be discouraging and will come as a shock to a great many shareholders who have built their hopes on the extravagant statements made by the previous management. Mr. Fisher, while pessimistic regarding the ore in the present workings, states that the situation is not hopeless and that there are indications of a large body of ore on the 600-ft. level. It will be necessary, however, to raise more money for development.

A meeting of the shareholders of the Northern Ontario Exploration Co. has been called for the purpose of considering proposals for the absorption of this Company by the California Exploration Co. The former company was originally organized by Bewick, Moreing & Co. to develop a number of claims in the Porcupine district, which were purchased from the Timmins-McMartin syndicate. Considerable money was spent in the development of these properties, but the results were disappointing and all work in Ontario was stopped. Subsequently, Bewick, Moreing & Co. became active in California and took over the old Plymouth mine, the development of which has been satisfactory. The Northern Ontario Exploration Co. has a considerable interest in this property, and it is now proposed to absorb the Company, giving the shareholders stock in the California Exploration Co. for their interest. The capital of the California company will be increased to £120,000, and the shares will be split to have a par value of 10s. each, shareholders of the Northern Ontario company receiving a total of 179,137 shares,

The prospectus of the Kirkland Lake Proprietary, Ltd., which was recently floated in London, is an exceedingly interesting document, and shows that even in these days of 'tight' money it is still possible to sell 'hot air' at a good margin of profit. This new Company is capitalized at £200,000 in £1 shares, and the subscription offer was 75,000 shares at par. It is stated that this amount was largely over-subscribed, and that the shares are now selling at a premium on the London market. It is understood that this Company will operate at Kirkland Lake, the new gold-mining camp of northern Ontario, and that it expects to take over the Tough-Oakes, Burnside, Wright, and Robbins properties,

MAP OF PRINCIPAL MINING DISTRICTS OF ONTARIO.

in all of which C. A. Foster is interested. The first is partly developed and seems to have excellent possibilities, while the others are prospects of uncertain value. The Company has acquired under a contract the benefit of all the arrangements now in course of negotiation or which may be hereafter entered into by Mr. Foster for properties in the Kirkland Lake district, including the right to take over the same at cost price and free of any commission or profit to Mr. Foster. For this understanding, Mr. Foster receives the sum of £25,000, and for every two shares over and above the present issue up to a further 50,000 shares, which may hereafter be allotted, an additional £1 in cash or one fully paid-up share at the vendor's option. The £25,000 will presumably be paid out of the proceeds of the issue of 75,000 shares, leaving approximately £50,000 as working capital. The directors are R. P. Cobbold and H. G. Latilla of London, and C. A. Foster of Halleybury. So far as can be learned, the idea is that the Kirkland Lake Proprietary will develop these

properties and such others as may be acquired, up to a certain stage, and then float them individually. It would appear that the \$25,000 which Mr. Foster receives will be only the beginning, this sum being paid for what might be termed Mr. Foster's good will. Of the four properties mentioned, the Tough-Oakes is easily the most promising, and development to date has succeeded in opening a considerable amount of rich ore. The Company is capitalized at 600,000 shares, par value \$5, of which Mr. Foster and his associates hold 450,000 shares. A short time ago, the Company endeavored to sell 50,000 treasury shares at \$4, but the flotation was a failure. It can be seen, however, that this is placing an exceedingly high value on this property, which is not warranted by the limited amount of development. No information has as yet been given regarding the ultimate disposition of the properties which will come under the control of the new Company, but for the sake of the English investor, it is to be hoped that the different companies will be floated at a capital that is commensurate with the requirements, and that the investor may at least 'get a run for his money.' The possibility is, however, that the promoters will get their share whether or not anybody else does.

DULUTH, MINNESOTA

WORK ON THE MESABI RANGE.—STATE LEASES.—WASHING ORE.—TENDENCIES IN EQUIPMENT.—WEATHER.—CANTON AND ALBERTA MINES.—IRON ORE SITUATION.

The past year has been a prosperous one for the Mesabi range in general, and the current year promises to be nearly as good. Indications point to a prosperous season for the Virginia district in particular. Jones and Loughlin are preparing to strip the Columbia forty. The Oliver Iron Mining Co. is drilling the Mesabi Mountain ground and it is figured that this will be stripped. The advantage of opening this is that it will give the Company a much better chance to get at the ore at lower levels in the Lone Jack and Ohio forties. The Mesabi Mountain property is a state lease, as is also the Minnewas, which is being opened as a shaft property. On this property, a concrete shaft is being sunk, and a temporary head-frame and hoisting plant has been erected. Work on the permanent plant is under way, which includes a steel shaft-house. The Company is also drilling the Rouchleau property, and it is expected that this will also be opened as well as some other ground north of the city.

A. B. Coates has given up his lease on the Madrid property in the city limits, but it is reported that the fee owners will operate the mine. About 100,000 tons has been shipped so far. A washing plant of small capacity was erected over the shaft to treat the lower-grade ore. This is said to have given successful results. The Oliver Iron Co. is also opening several properties at Virginia and other places on the range. This policy is said to be due to the fact that the Company will relinquish the Hill ore lands and will have other property opened to keep up reserves. The policy seems to be to open all property that is leased, as much as possible, to avoid paying royalties on idle mines, and this has resulted in a practical cessation of work at several places where the Company owns the fee. This has given a temporary set-back to the towns in the vicinity depending on the mines for sustenance. The state leases are being operated more vigorously, with the result that the revenues of the state will be materially increased from royalties. One mine, the Hill Annex, is on a school property, and it is said that the school fund will receive over \$12,000,000 from this one mine. The Jones & Loughlin Co. has started operations on a large orebody near Grand Rapids, and has installed a hydraulic dredge. This is said to have demonstrated its practicability for removing the overburden in the short time it operated this fall. The orebody at this property is large and a part of

it will require washing. A large concentrating plant will be built to handle this ore. Several companies have been conducting experiments along this line, so that the near future will see several more washing plants at work. The drier operated by M. A. Hanna & Co. at the Brunt mine, at Mountain Iron, is said to have been successful in reducing the moisture content from about 18% to about 3%, although the question of what effect this drying has upon the formation of fine material and the behavior of the ore in the furnaces is not mentioned.

The general trend of new construction work is toward permanency. Wooden head-frames are practically a thing of the past. Concrete is taking a prominent part in all new construction both at the surface and underground. Mechanical power is being used to a greater extent, but power-plants are hardly keeping pace with developments in other localities, due probably to the comparatively shorter life of the underground mines. For the open-pit mines, no extensive plant is required outside of the steam-shovel equipment. Experiments are being conducted along various lines to improve methods, and safety and public welfare are given more consideration than they have received in the past. The use of electric power is becoming more general, and new sources are being developed. It is thought that the pumping of the majority of the mines will in course of time be done with electric power.

The Hull-Rust mine shipped last season 3,457,608 tons of ore, which is a record for a season's shipment from one mine.

The weather this winter has been remarkably warm, and the first permanent snowfall occurred after the first of the year. This is not enough as yet to help loggers to any extent, and it is feared that mining-timber contractors will have trouble in getting out their supply in time to fill their contracts. This has not affected the price as yet, which is ranging around 4.5c. per lineal foot for 16-ft. timber from 7 to 9 in. at the small end.

The Pitt Iron Mining Co. has leased the Canton forty, adjoining the Miller mine at Aurora, which it is operating, and has started sinking a shaft on the property. The Canton forty is owned by the Oliver Iron Mining Co. The orebody at the Canton is contiguous to that on the Miller, and can be most advantageously worked in conjunction with that of the Miller. The Alberta mine, which has been operated by the Minnesota Mining & Development Co., has been shut down, and the lease reverts to the state, which owns the fee. The Lily Iron Mining Co., from which the Minnesota company sub-leased the property, is suing for an injunction to prevent the Minnesota company from removing the machinery until liens against the latter have been satisfied. The Alberta mine is in the Virginia district.

The iron-ore situation at the present time is in a rather uncertain state, practically no sales for 1914 delivery having been made as yet; so whether the prices will be lower the coming season is a matter that is causing considerable speculation. The recent placing of orders for large tonnage of rails is conducive to a more optimistic feeling. The Cuyuna range continues very active. Considerable exploration work is under way, and the area of ore-bearing formation is constantly increasing. The city of Brainerd opened bids on January 5 for exploring and mining the property bequeathed to it by the late Judge G. W. Holland. The county commissioners of Crow Wing county accepted the bid of the Long-year Exploration Co. to explore the county poor farm. The Company pays \$100 as rent and agrees to drill nine holes per year. It gets a 50-year lease at 30c. per ton, and a minimum tonnage of 10,000 tons the first year, 20,000 tons the second, 30,000 tons the third, and 40,000 tons each succeeding year during the life of the lease.

The output of iron for the month of December is reported at 1,983,607 tons, or 63,987 tons per day, which is a decrease from the November production of 2,233,603 tons.

NEW YORK

PROFIT-SHARING BY EMPLOYEES.—YUKON GOLD, NEW YORK & HONDURAS AND GERMAN POTASH SYNDICATE.—ALASKAN COPPER.—MEXICAN AFFAIRS.—ARMOR PLATE MANUFACTURE.—INSPIRATION COMPANY.—COPPER SITUATION.

The International Nickel Co. is following the example set by the United States Steel Corporation, to which it is distantly related, in offering to allow its employees to purchase a limited number of shares at \$110, paying for it in instalments from their salaries. Dividends will begin as soon as the first instalment is paid, and the employees will receive extra compensation amounting to 5% of the stock subscribed for, so long as they retain their stock and remain in the employ of the Company. As International Nickel common stock is paying 10% per year, the employees will get what amounts to 15% a year on their holdings. The permissible number of shares varies according to length of employment and salary received, amounting to 10 shares in the case of those receiving over \$4000 per year, who have been in the Company's service 10 years or more.

At the annual meeting of the Yukon Gold Co., all the re-

the United States was going to do about it. Naturally, the answer has not been made public, but it might have been an inquiry as to what the European powers did when the Balkan states embarked on two wars in the face of their prohibition. We are now paying pensions amounting to \$175,000,000 per year on account of previous wars, and the American public is not likely to see in the losses of foreign investors any compelling reason for intervention, no matter how awkward our diplomatic position may be, the more especially since the interest is merely suspended, not repudiated. If the warring factions in Mexico would only carry on their fighting without ripping up the railroads, the mining companies—most of them, at least—would be able to get along fairly well.

Some time since I wrote of the possibility of the United States Government embarking in the armor-plate business, and a bill appropriating \$8,000,000 for the purpose will soon be introduced in the House. Sir Robert Hadfield has been in this country for some time, presumably on account of the possibility of securing the use of Hadfield steel, which is much cheaper than that now used in the manufacture of projectiles. In this he has been unsuccessful, since it was deter-

COPPER CLIFF SMELTER, OF THE CANADIAN COPPER CO., OF THE INTERNATIONAL NICKEL COMPANY

tiring directors were reelected. The New York & Honduras Rosario Mining Co. has declared a dividend of 2% payable January 24, following its dividend of 3% paid December 30, 1913. The New York representative of the German Potash Syndicate has announced that, at the general meeting in Berlin, all the members waived their right to terminate the agreement at the end of 1915, and it is therefore extended to 1925. (A cable to San Francisco on January 21 stated that the German Government had appropriated \$125,000 for an exhibit of potash minerals at the Panama-Pacific Exposition in 1915.)

The Kennecott Mines Co. has paid a dividend of \$1,000,000, bringing its total distribution to \$5,000,000. The Tacoma plant of the American Smelting & Refining Co., where the Alaska copper ores are treated, was reported to have been shut down on account of a strike, but as a matter of fact nothing more serious occurred than a little inconvenience, and the plant is running. The total copper now coming from Alaska amounts to a respectable quantity, and when the affairs of that 'distressful country' are finally adjusted, it is likely to increase considerably.

Mexico has been so much discussed that only strong provocation will lead one to reopen such a sore subject. The needed stimulus has been supplied by the announcement by President Huerta that payment of interest on all domestic and foreign indebtedness will be suspended for six months. As something over \$300,000,000 worth of bonds is largely held in Europe and America, this is touching the pocket nerve with a vengeance. European governments lost no time in asking what

mined a short while ago to continue the use of the more expensive forged projectiles. It will be interesting, therefore, to see whether the Hadfield steel will be adopted for armor plate in the government plant. It may be said that Sir Robert's wife is American, since he married the sister of George W. Wickersham, attorney general under ex-President Taft. Well informed persons are of the opinion that the Hadfield steel is much cheaper and just as good, since it has been adopted by the British admiralty.

The Inspiration Consolidated Copper Co., in its report to the New York Stock Exchange for November 30, 1913, shows cash on hand amounting to over \$2,000,000. In spite of this, it is reported that the Company will have to do some new financing in order to complete its scheme of new construction, which has been considerably extended as compared with its original plans. The 4-mile branch, to connect the plant with the Arizona Eastern railway, will be built by the Company instead of by the railroad people as at first planned; and additional lands will be bought for the storage of tailing and to increase its water-supply. The surface plant and work underground will be on a more extended scale, and it is said that plant will be provided for the recovery of the oxidized copper minerals, which cannot be caught in the flotation plant. The Company has \$6,000,000 in bonds outstanding, but it has over 500,000 shares which are available for the raising of new funds.

Two seats on the New York Stock Exchange were sold for \$50,000 each on January 19. Sales on the Exchange on January 22 totaled 783,300 shares.

BRITISH COLUMBIA

THE SEYMOUR RIVER MINING DISTRICT.—DISPUTED PLACER CLAIMS IN THE CARIBOO DISTRICT.

The mineral resources of that portion of the province of British Columbia, situated to the north from the head of the Seymour arm of Shuswap lake, have been receiving more serious attention from prospectors during the past season than formerly. Although handicapped to such an extent that the transportation of supplies by pack horse has been costing 8c. per pound from the village of Seymour arm to McLeod's camp, a distance of about 22 miles by trail, development work has been carried on all last summer on the Camp McLeod group of claims, and assessment work has been done on the Copper King and Bass groups. The camp is locally known as the Cotton-belt, because the first discovery of mineral, in the form of a heavy gossan outcrop, was made by a negro prospector about 20 years ago, at the time when he and other stampederes to the big bend of the Columbia river were traveling to the placer diggings on creeks emptying into that river, following an Indian trail that crossed the summit between Seymour and Columbia rivers near the scene of present activity. The discovery resulted in the staking of the Cotton-belt group of claims, and the performance of sufficient assessment work to obtain crown grants or patents to the ground. Later, the attention of some trappers, who hunted and trapped every autumn and winter in the neighborhood of the Cotton-belt camp, was attracted by other gossan outcrops on the mountain side, which were found to overlay copper ore as well as galena. Several claims were staked and assessment work was done; but at that time smelting ores were useless as there were no smelters nearer than Trail, on the lower Columbia river, and want of transportation facilities to the Canadian Pacific railway. The progressive policy adopted by the provincial government in encouraging and aiding the construction of new railways and good wagon-roads, is responsible for the renewed activity in the development of the claims last summer. The miners argued that, if a fair tonnage of ore of commercial grade was exposed, the construction of a wagon road could be secured, followed later by railroad to the head of Seymour arm, where water transportation could be used to the Canadian Pacific railway at Sicamous, and the ore shipped to the Trail smelter.

The rock formations of the range of mountains in which the occurrence of galena, copper, zinc, and magnetite ores are found, are mica, schist, and crystalline limestone. The orebodies occur both as contact deposits between these rocks and as veins in the mica schist, their lines of strike and dip being conformable with the bedding planes of the country rock. They strike nearly true northwest and southeast, and dip at an angle of 45° toward the northeast. So far, work has shown that there are at least three distinct parallel orebodies in the Cotton-belt mountain, one of the earliest discovered, on the summit at an elevation of about 6000 ft. above sea-level; another at about 1700 ft. lower elevation, and the third about 300 ft. still lower. All are on the southwest slope of the mountain, looking toward the north fork of the Seymour river and Deep creek, one of its tributaries. The persistence and length along the lines of strike of each of these orebodies are quite unusual. For example: the outcrop of the Cotton-belt orebody is exposed by cross-cut trenches on the plateau, along the summit of the mountain, for a distance of nearly two miles; the outcrop of the second or Copper King orebody can be traced across five claims or about 7500 ft.; and that of the third or Camp McLeod orebody has been exposed in open-cuts made about 100 ft. apart for a distance of 3000 feet. The Cotton-belt orebody is composed of some galena and zinblende in a matrix of magnetite; the Copper King orebody is composed of iron pyrite and chalcopyrite in a quartz matrix; and the Camp McLeod orebody is similar in composition to the Cotton-belt,

only the amount of galena is greater.

Considered from a commercial standpoint, the ore in the Copper King orebody apparently has an advantage over the others because it could be easily concentrated, while the other ores containing galena, zinblende, and magnetite would present a more complex problem. The tonnage of ore in the Copper King should be considerable judging from the width of the outcrops, which at several points exceeds 12 ft. The Camp McLeod orebody varies in width from about 3 to 10 ft., and the Cotton-belt averages about 3 feet. In addition to the extensive surface work that has been done, underground work on the Camp McLeod group in 1913 included an adit driven along the strike of the lode, a distance of 65 ft.; on the Bass group the incline shaft has been extended to a depth

MAP OF BRITISH COLUMBIA.

of 50 ft.; and on the Copper King group a short adit has been driven to cross-cut the orebody at depth.

The supply of timber for mining and domestic purposes is abundant on all the properties except at the Cotton-belt group, situated on the extreme summit, and about 500 ft. above timber line. Deep creek, a tributary of the Seymour river, will afford practically an unlimited supply of power, as it is quite a large stream having a fall of several hundred feet in about a mile, and as it flows through Camp McLeod property, is easily accessible for use.

The hydraulic plant formerly operated at Bullion, in the Cariboo district by H. B. Hobson, for a company composed of Canadian Pacific people, was purchased several years ago by the Guggenheims. A new ditch was partly made, but work was stopped at the property in 1907 or 1908. From 1894, a total of over \$2,000,000 was recovered from the gravels. The water supply was always insufficient to work over 50 or 60 days per year. The following season, after suspension of work, it was alleged that the Guggenheims had not complied with the provincial mining regulations. Mr. Hobson then resumed work, but was soon mixed up with litigation which was settled before his death. In 1913, John Hopp assumed that the Guggenheims had not fulfilled the hydraulic regulations, and re-located the claims. Then E. T. Ward claimed to have bought them from the Guggenheims, and is soon to appear before the authorities to endeavor to oust Mr. Hopp. Such complications are almost unknown in British Columbia, and it is hoped that work will soon be resumed.

General Mining News

ALASKA

CORDOVA

The Mother Lode Mines Co., with property adjoining the Bonanza, has started to sled some high-grade ore to the railroad for shipment to the Tacoma smelter. The Golden Eagle claim at Golden, in the Port Wells district, has been leased on option to Edwin Grisct, of Cordova. The lease is for four years, with a royalty of 10%, and a purchase price of \$30,000. The mine is at tidewater and can be worked by adits. About \$15,000 of ore has been opened.

FAIRBANKS

Winter dumps are being taken out on Fairbanks creek, and several outfits are doing well. Work on the lower end of Goldstream is as active as in former years. After many hardships during a 21-day trip, P. Breen and A. Allendale, of Council, Seward Peninsula, reached Fairbanks on December 17 with their dog-team. They averaged 50 miles per day. Their destination is Shushana.

The geology and mineral resources of a part of the Yukon-Tanana region, including the gold placers of Rampart and Hot Springs, are described in a report just issued by the U. S. Geological Survey as *Bulletin 535*, by Henry M. Eakin. Placer gold was discovered in the Rampart district probably

ELLAMAR MINE, ELLAMAR, ALASKA.

as early as 1893, and since 1896 systematic mining has been carried on, the first claim worked being on Little Minook creek. Later, as the area being prospected increased, placers were located and mines developed on the tributaries of Baker creek, and still later on Sullivan creek and neighboring streams tributary to Patterson creek. The stream gravels have furnished the greater part of the gold output of the Rampart and Hot Springs districts. Smoothly rounded pebbles of cassiterite, the oxide of tin, are found with the gold in the Sullivan creek placers near Rampart. The area in which the cassiterite occurs is small, being less than a mile in its longest direction. The tinstone or stream tin, as it is commonly called, varies in amount with the gold, the placers commonly being rich or lean in both minerals. In the richest spots as much as half a pound of tin to the pan is reported, which at the present price of the ore would give the gravels a value, not allowing for costs of mining or transportation, of \$18 to \$20 per yard, according to assay. Gravels that contain as little as 9 lb. of cassiterite per yard are being mined profitably in the York region. A copy of *Bulletin 535* may be obtained free on application to the director of the Geological Survey, Washington, D. C.

JUNEAU

The work of developing and equipping the Alaska Gold

Mines property continues without interruption. No. 1 shaft is completed from the Sheep Creek adit to the surface. A hoist has been installed at No. 10 level, enabling men and supplies to be handled coming through the Sheep Creek adit and up the shaft to the Perseverance mine. This adit was driven 600 ft. in December, and connection should be made with the vertical shaft early in April. All levels from No. 5 to 10 inclusive are being driven east and west. By May all the main drifts will be driven west to the surface. No. 2 power-plant on Salmon creek is now at work, and No. 1, near the beach, has the first unit completed. Work on the dam was stopped in November, but will be resumed in April. Removal of rock for the crushing and mill foundations will be finished in about three weeks. Bunk, boarding, and club houses for the employees have been fully equipped with all necessities.

SHUSHANA

There is a difference of opinion between those who have been over it, concerning the McCarthy-Shushana route. Some say that it is a failure, while others declare it is all right. A number of men are leaving the district.

VALDEZ

The 1913 season in the country tributary to Cook's inlet and to Seward on the Kenai peninsula, at the head of Resurrection bay, was marked by steady progress in the mining industry. This portion of Alaska is notable for free-milling high-grade gold quartz veins, hydraulic and dredge mining, as well as for the Matanuska coalfields. In the first mentioned class of mining the following properties were producers, the Gold Bullion, Gold Quartz, and the Milo Kelly, situated in the Susitna district, tributary to Cook's inlet, also the Kenai Alaska Gold, Skene Lechner, and the Primrose properties tributary to Seward. Hydraulic mining was conducted successfully on Cache creek, a tributary of the Big Susitna river, but dredge mining on the Kenai river was suspended pending examinations being supervised by Mr. Tripp, of Juneau. Prospecting on Grant lake, near the 25-mile post on the Alaska Northern railway, resulted in exposing some high-grade gold quartz, of which a shipment of about 4 tons was sent to the Tacoma smelter by James R. Hayden in November last, the returns from which are reported as being quite satisfactory.

ARIZONA

The state mine inspector, G. H. Bolin, has issued his annual report at Phoenix. He and his deputies, William Farrell, John Harper, and J. C. Wilson, made 266 inspections of 84 mines during the past year. The total number of men employed in those mines was 13,933, of which 2664 were above ground and 11,269 below. They are divided among the counties as follows: Cochise, 4448; Gila, 2458; Graham, 35; Greenlee, 3133; Maricopa, 159; Mohave, 426; Pima, 177; Pinal, 1786; Santa Cruz, 188; Yavapai, 907; and Yuma, 189. During the year, 66 men were killed in Arizona mines, and there were 70 accidents classed as serious. The Copper Queen heads the list of employing companies, with 346 men above ground and 2006 below. Other large employers are: Arizona Copper Co., Ltd., 169 above and 792 below; Calumet & Arizona, 90 and 1387; Ray Consolidated, 228 and 1357; Inspiration, 162 and 458; Miami, 81 and 783; Old Dominion, 125 and 409; Arizona Copper, 140 and 501; Detroit Copper, 133 and 926; Shannon, 170 and 275; and United Verde, 34 above and 555 below.

The inspector summarizes the industry as follows: "Mining in Arizona was never more active than at present. The principal porphyry companies that are operating actively are the Miami, Inspiration, and Ray. These mines produce low-grade ore and are mined by the caving and shrinkage system. On April 17 five men were killed by an air-blast in the Miami mines. After investigating this disaster, Mr. Harper and I came to the conclusion that the stopes were drawn

too much, thereby leaving too much open space between the back of the stope and the loose ore in the stope. Instructions were given not to allow more than 10 ft. of space between loose rock and the back of stope in future. The number of fatalities in the Ray mine has decreased 200% or more. The narrowing of the stopes, which was ordered by this department, is responsible in a great measure for the decrease. Considerable improvement has been made in the ventilation of the mines in the past year. The managers of the larger mines, by installing large electrically driven fans which force pure air into parts of the mine where it was impossible for a miner to do a shift's work, have found that such parts can be cooled to such an extent that a miner can do much more work without impairing his health to a marked degree. Waste and timber in parts of mines that have been exhausted, or where the ores have been extracted, are responsible for a great amount of heat encountered in mining. More attention is given to the safety of employees at present than before. 'Safety-first' departments have been organized by all the large operating companies. Regular meetings are held, and the men in charge of operations exchange ideas in order to install devices which will prevent accidents."

GILA COUNTY

(Special Correspondence.)—Recent assays of tailing from the Inspiration flotation plant show as low as 0.64 and 0.13% copper. The towers of the Roosevelt power-line are near the mill. During the past week two men were killed by falling from one of them. The American Bridge Co. expects to receive 600 tons of structural steel per week for the new mill. There is nothing special to report on underground work in the mine.

Miami, January 16.

MOHAVE COUNTY

During December the Tom Reed mine produced gold worth \$109,000, and in 1913 a total of \$1,300,000. About \$800,000 was paid in dividends. The claims in Copper cañon, Cedar Valley district, known as the Molybdenite group, have been optioned to J. H. Conway, of St. Paul, Minnesota.

SANTA CRUZ COUNTY

According to *The Oasis*, of Nogales, the present situation of mining in the county is as follows: Ore shipments have been made from the Three R mine in the Patagonia mountains; in the Chief, near the Three R, a promising orebody has been developed; in the district are a number of good properties, among which is the Buena Vista group, operated by the Arizona-European Mining Co.; just across the mountains is the well known World's Fair mine; at Mowry, the Red Mountain Mining Co. is busy developing its claims, and a concentrating plant will probably be erected; the Duquesne mines, near Washington camp, 20 miles from Nogales, are shipping ore regularly; in the Santo Niño, near Duquesne, the Havalena Mining Co. has had good results, but litigation has stopped work temporarily; a group of claims in the Patagonia mountains is being actively prospected by J. F. Campbell, A. S. Henderson, and L. Koeller; other good claims in these mountains are the Volcano, Sunshine, Morning Glory, Bluenose, Cunningham, Buffalo, Skibo, Hardshell, and Flux; there are also several interesting properties in the Santa Rita mountains, among which is the Elephant Head, employing 125 men, and shipping ore, while a reduction plant is contemplated; rich silver-lead-zinc ore has been opened in the Mark & Louis Lulley mine; the Wandering Jew mine, worked many years ago by the old monks, is in this district; litigation has suspended work at the Alto; ore is being shipped from the Royal Blue; on the south side of the mountains are the Trenton, Santa Rosalia, Ivanhoe, Mammoth, and Blue Lead claims, which are opening well; on the east side the Mansfield Mining Co. has cut a large shoot of copper-gold ore at 400 ft.; the American Boy, August, Hosey, Happy Jack, Gringo, and Victor are near by; near the Pima county line, on the north side of the

mountains, the old placer deposits are being worked by a few men; southwest of Greaterville the Onyx King Mining Co. has developed a large deposit of chalcedony; the Oro Blanco district, in the west of the county, is gold bearing, and there are the Austerlitz, Montana, Warsaw, Oro, Oro Blanco, Grubstake. Tres Amigos, Oro Fino, and Progressive mines; the first named has a mill working; the Montana and Progressive have opened large tonnages of ore; and near the Mexican boundary the Gold Cañon Placer Mining Co. has been hydraulicking, but a cloudburst put the plant out of commission temporarily.

CALIFORNIA

BUTTE COUNTY

Dredging companies know the value of the ground on which Oroville is built, and Lawrence Gardella, a dredge operator, and the North California Mining Co. are trying to have an existing ordinance repealed, whereby they can dredge

DREDGE TAILING AT OROVILLE.

a 40-acre tract within the town limits. They propose to give the town an 8-acre park in return for the privilege of recovering the gold contained in the area; but the park committee argues that it will have only a rock pile on its hands if this is done.

CALAVERAS COUNTY

It is stated that negotiations are pending for the sale of the Keystone Union, and other claims by the Calaveras Copper Co. at Copperopolis.

LASSEN COUNTY

Mining at Hayden Hill has been quiet for some time; but the Lassen Mining Co. is to resume work in the spring, while others are preparing for operation.

NEVADA COUNTY

Development in the Champion mine, owned by the North Star company, is said to be very satisfactory. The Black Bear stamp-mill in the Rough and Ready district is working again, this time on ore from the Forlorn Hope vein, which junctions with the Black Bear.

PLACER COUNTY

Work is to be started soon at the Spring Garden and Packham Hill claims near Forest Hill. An active season is anticipated for the district.

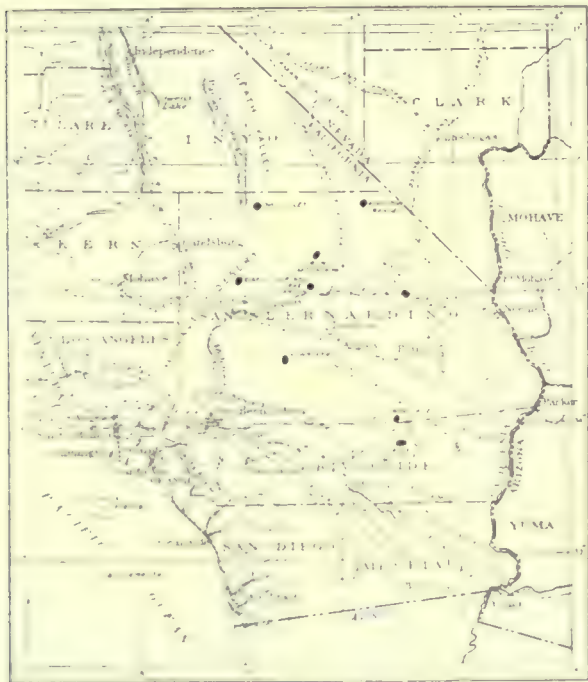

It is probable that Eastern capital will be secured to reopen the Southern Cross mine, near Humbug cañon. The mill and other buildings were burned last summer. So far this winter, no mines near Alta have been worked.

PLUMAS COUNTY

At Johnsville, the Jamison mill is to restart crushing, there being ample water in the reservoir. An air-compressor is being installed by lessees at the Tefft mine, near Claremont peak. The machine will be driven by water-power. Twenty-seven copper claims in Lights cañon have been filed for record at Quincy for the Nevada-Douglas Copper Company. The Mohawk copper mine in Last Chance cañon, near Vinton, has been sold to Salt Lake people for \$125,000. The mine was opened by M. J. Daly, who has shipped ore worth \$55 per ton. E. A. Ludwick is manager.

SAN BERNARDINO COUNTY

The Atolia district was the second largest producer of tungsten ores in 1913, and still makes a larger production of scheelite than any other district in the world. Nearly all the output was produced by the Atolia Mining Co., but small

MAP OF SOUTHERN CALIFORNIA

quantities were also produced from several mines at Atolia and the Stringer and Randsburg districts on the north.

SHASTA COUNTY

The Friday-Lowden group of copper claims has been bonded by an English Columbia company, called the Silver Tip Mining Company. The property adjoins the Mammoth holdings. The deal was made through S. E. Bretherton. Twelve men are working at the Mount Palby company. A new tunnel, and 10 tons of rich ore is sent daily to the Gambrinus mill. A compressor is being installed at the Silver Mountain mine. Cross-cutting is to be done at 140 ft. The Silver Mountain district is hoping for an active season. At 1000 ft. in the Esperanza mine, a seam of good coal has been exposed. A. J. O. Ward is superintendent.

SEKIYU COUNTY

All the hydraulic mines are working fine, and there is plenty of water. The dry gulch, which was making good clean ups the first time for six years, owing to shortage of water.

TRINITY COUNTY

The Globe 20-stamp mill, at Bodfish, treating 100 tons of ore per day, with high recovery. Fifty men are employed at the property. Wallace McGee is manager. D. W. Shanks has taken charge of the Trinity Consolidated Mines Co.'s Union Hill and Hupp placer properties. The plate for the Lagrange Syphon at Stuart's Fork was landed on January 16, and the break will soon be repaired.

TULARE COUNTY

At the Hazel Dell mine, near Coalinga, a 500-ft. crosscut has been driven, from which drifts are cut 310 and 120 ft., east and west. In the latter drift the ore-shoot is 32 in. wide, worth \$37 per ton. The ore contains a high percentage of galena. The Jamestown Exploration Co. has an option on the Carlin mine, and further development is proposed. The Columbus, near Tulare, will probably be reopened. The 2200-ft. adit at the Shawmut, used for conveying ore to the

mill, is being enlarged preparatory to using electric locomotives instead of horses. Work at the Hope is satisfactory, and a Huntington mill will be erected. G. W. Weston is manager.

YUBA COUNTY

(Special Correspondence.)—The report published in this journal of January 10, relative to the loss of two drills operated by the Guggenheim interests, is not quite correct. One machine of the Keystone type was wrecked, but not lost. It was washed down the river about 1200 ft., and has since been refitted.

Smartsville, January 15.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The electric trolley system at the Capital mine was brought into commission on January 12. Considerable development work is planned. The Onondago Mining Co. will operate the Ruler property through the Capital adit, a perpetual right of way having been secured. E. C. Bauman is manager. Two well known miners fell about 600 ft. in the Capital mine on January 15 and were killed. The machinery at the Rosebud mine on Democrat mountain was started this week. Cross-cutting is under way 800 ft. from the portal of the adit, to cut the east extension of the Astor vein. G. W. Teagarden is manager. The Butler property is the scene of a promising find. The ore-shoot is 5 in. wide and assays return 290 oz. silver per ton. H. W. Kirby is owner. Hanson & Co., leasing on the Anamosa mine on Columbian mountain, have uncovered a 20-in. ore-shoot and a test shipment returned 150 oz. silver per ton. A carload shipment will be sent to the Argo smelter next week. It is stated by J. B. Ballantine, in charge of installing machinery at the Pelican mill, which is being provided with the Edison method of ore dressing, that ore treatment will be started within two weeks. The Mendota mill at Silver Plume, which has been in almost continuous operation for 12 years, has been closed down temporarily. Pending the starting of the same, Stephens Bros., the operators, will carry on development on the Frostburg vein, work to be done above the Victoria adit level. Work has been resumed on the Gold King property situated on Saxon mountain. E. O. Bonham is in charge.

Georgetown, January 12.

OURAY COUNTY

Development at the Mountain Top is very satisfactory. No. 2 shoot has been opened for 300 ft. and is from 2 to 3 ft. wide, averaging from \$30 to \$40 per ton. Metal contents are: gold \$1, silver, 35 oz. and lead, 12 per cent.

TETER COUNTY (CLEAR CREEK)

Sinking is under way in No. 1 and 2 shafts of the Portland mine, from 1600 to 1750 ft. Two shifts are employed. Lessees at the C. K. & N. mine are making a large output of \$30 ore. Control of the Jo Dandy Mining Co. was sold on January 16 to William MacDonald, of Albany, New York, and H. C. Gilderhouse, of St. Louis, Missouri, for \$100,000. This was paid to Allen L. Burris, of the El Paso Consolidated company, representing a large number of shareholders. Two cars of ore from the South Burn mine returned \$20 and \$12.70 per ton, respectively. Two shifts of miners are working in a drift from the Feller crosscut in the Rosevelt drainage tunnel, to develop the C. K. & N. vein. Results are promising so far, but the flow of water is 800 gal. per minute. From the drain tunnel the flow is now 7200 gal. per minute.

IDAHO

BLAINE COUNTY

The Wilbert mill, 40 miles from Arco, has been shut down owing to the low price of lead ore. Development is to be continued.

BOISE COUNTY

The Liberty Mining Co. has been organized at Boise to work placer ground in the Boise basin, about 30 miles north-east of that city. The officers of the Company are A. E. Small, president; James Cathcart, vice-president; M. A. Small, secretary and treasurer; E. W. Barry, H. L. Fisher, Charles F. Baxter, and J. C. Buckholz, directors. The company has a large tract of virgin placer ground on Moore's creek, two miles below Idaho City and adjoining the Boston-Idaho Gold Dredging Co.'s ground. The property consists of 402 acres of bar and bench ground and is situated well above the bed of Moore's creek, affording an excellent dump for the ground, which will be worked by the hydraulic method. Two electric pumps of 500-hp. capacity will be installed, capable of delivering water at 60-lb. pressure. The plans include the construction of a large storage reservoir, which will have a capacity of 13,500,000 gal. Frank E. Johnesse, a Boise mining expert, has made a thorough examination of the property and reports an average of 24.7c. gold per cubic yard. Operations will commence in May or June. The working season here is from March to November, inclusive.

CUSTER COUNTY

The Lucky Boy Gold Mining Co.'s properties at Custer have been bonded and leased, with a purchase option, to Colorado Springs men. The various claims have been opened by 25,000 ft. of development, and the mine, stamp-mill, and cyanide plant have been fully equipped. Previous to the shut-down the mines produced \$7,000,000 in gold and silver.

LEMHI COUNTY

Great activity is reported from the lower Salmon mining districts. One lessee on Shoup is extracting ore from an 8-in. vein which will yield over \$250 per ton in gold. This ore will be treated at the new mill and cyanide plant at Pine creek. Mr. Gonder, who owns property on Sheep creek, in the Gibbonsville district, is in Nevada on a trip for new machinery. The A. D. M. people at Gibbonsville will probably install a new compressor in the spring. The ore opened would pay for the installation of a mill. On the Kitty Burton, at Ulysses, other lessees are equally active. Though the ore is not high grade, it is reported that they are making money.

SHOSHONE COUNTY

The Clearwater Gold & Copper Mining Co. has developed a large tonnage of ore in its mine on the upper Clearwater, and transport is difficult. According to Sam Seidenfeld, a large stockholder, it is proposed to construct an aerial tramway 12 miles long to cross the Bitter Root divide between Montana and Idaho. The tramway would have a capacity of 24 tons per hour. About 4000 ft. of work has been done in the mine at a cost of \$80,000. The Stewart Mining Co.'s earnings in December were \$65,000, making a total of \$226,000 for the last quarter of 1913. The last half-year's profits were \$435,000, from which \$277,000 has been paid in dividends.

The National Copper Co. at Mullen, is erecting a 500-ton plant, the ore being crushed with rock breakers, rolls, and Hardinge mills to 30 mesh. This is then concentrated. The sand product is reground in other Hardinge mills and then the whole product passed to Dorr thickeners to be dewatered as low as possible. The underflow goes to a flotation plant, the overflow being returned to the head of the mill. The tailing passes to other Dorr thickeners, the overflow from which is mixed with the underflow from the first series of thickeners which goes to the flotation boxes. The underflow from the second series of thickeners goes to the tailing dump. All of the concentrate from the tables and Minerals Separation plant passes to a Kelly filter to be dewatered.

MICHIGAN

HOUGHTON COUNTY

(Special Correspondence.)—Organized labor throughout the United States has sent at least \$750,000 into the Michigan

strike district since the inception of the labor difficulty here last July. How much of it ever reached the men who went on strike is a question which is agitating the minds of officials who are investigating the trouble. The largest contributions to the maintenance of the strike came from the Butte branch of the Western Federation of Miners. A similar contribution had just been made to the strikers in the Bingham district, Utah, in 1912. The Western Federation of Miners has not received any contributions from Bingham, or the Homestake, where there was a strike some years ago. Further trouble has arisen with the Western Federation, and it appears that Walker of the Illinois Federation of Labor and the American Federation of Labor, is trying to consolidate the Western Federation and the United Mine Workers of America.

At 18 of the copper mines there is a total of 8724 men employed, against 13,514 before the strike, which started on July 23. 'Moyerism' seems to be the only issue at stake now, and the mining companies will not recognize the Western Federation of Miners. Charles H. Moyer and others have been indicted on the charge of conspiracy.

Houghton, January 15.

MONTANA

LEWIS AND CLARK COUNTY

Ten to fourteen inches of high-grade galena has been opened at the bottom of the incline shaft of the Franklin mine, at a depth of 280 ft. From 15 to 20 men are employed.

MADISON COUNTY

The Big vein has been cut 225 ft. north on the 500-ft. level of the Corbin Copper Co.'s Blowout property at Rochester. A large flow of water was also cut, and additional pumps will be installed to handle the 800 gal. per minute flow. The Company is developing its Gambrinus mine at Butte with satisfactory results.

SILVERBOW COUNTY

The North Butte company has acquired 900 additional acres of Butte territory for which it has paid \$1,000,000 in cash and 20,000 shares of stock. This property has been in process of acquirement for nearly two years, and the \$1,000,000 of cash has come out of earnings, and at the same time the Company has added to working capital a total of about \$1,000,000.

During 1913 the Butte & Superior Mining Co. treated 307,957 dry tons of ore, which yielded 104,214 tons of concentrate, containing 102,002,039 lb. of zinc. The recovery averaged 83.08 per cent.

NEVADA

The new mining law regarding the employment of men about mines who cannot speak or understand English, referred to in the last issue of this journal, is to be tested in the courts. The Tonopah Mining Co., W. H. Blackburn, manager, is representing the other mining companies at Tonopah in this argument.

ESMERALDA COUNTY

During the past week the shaft of the Darms Coal Mining Co., at Coaldale, passed through 14 in. of good coal at 300 ft. The shaft will be sunk deeper.

HUMBOLDT COUNTY

At the Broughton-Newman lease on the Original Rochester estate, controlled by W. C. Pitt, C. H. McIntosh, and others, the lessees have shipped ore worth \$124 per ton in silver and gold. A 140-ft. adit has cut the ore-shoot, which is from 4 to 8 ft. wide. There is estimated to be a total value of \$70,000 in sight. The Octopus claims have been bonded to Oakland and Spokane people for \$50,000, with a cash payment of \$2500. Ore opened is 9 ft. wide, 3 ft. being worth \$40 and the balance \$12 per ton.

LINCOLN COUNTY

The Day-Bristol Consolidated Mining Co., of Pioche, is in

the hands of a receiver, H. E. Freudenthal. The Consolidated Nevada-Utah Corporation complains that the Day-Bristol company's properties have been mismanaged during the past two years and money has been spent extravagantly.

LYON COUNTY

The Mason Valley smelter, at Thompson, received 4075 tons of ore during the second week of January, and shipped 240,000 lb. of blister copper. A 60-hp. gasoline engine and air-compressor is being installed at the Smith Valley mine. Rich gold ore has been opened by Bovard and Knight on their Pumpkin Hollow ground. Development at the Burlington-Nevada mine is satisfactory.

NYE COUNTY

The mines at Tonopah, during December, produced 46,115 tons of ore worth \$937,480. The total for 1913 was \$10,016,968, and \$63,602,133 to date. At the Belmont, 14,603 tons was treated, yielding 4019 oz. gold and 370,354 oz. silver, with \$171,866 profit. The Tonopah company's output was 11,890 tons, yielding 227,523 oz. bullion and 135 tons of concentrate worth \$46,250. The profit was \$133,125. The West End mill treated 4869 tons at a profit of \$42,211. From the Jim Butler

mill is treating 170 tons per day. Placer mining at Round Mountain yielded \$100,000 last season. D. Llewellyn and associates recovered most of this.

STOREY COUNTY

The water in the Con. Virginia winze was down 180 ft. below the 2500-ft. level on January 21.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—A gasoline hoist, air-compressor, and machine-drills are being assembled at the Lincoln property. The Maud shaft is being sunk a further 160 ft., making 700 ft. in all. Development at the Pacific property is to be extended. The Deadwood plant is working full time. Work is going on steadily in the main drainage and transportation tunnel of the Oaks Co. which will eventually be under the large mines of the district at depths of from 1400 to 1800 ft. During 1913 the Socorro mine produced about 25 tons of gold and silver bullion, and a good tonnage of high-grade concentrate.

Mogollon, January 12.

TONOPAH, NEVADA.

mine 1971 tons was shipped at a profit of \$13,451. Other contributors to the December total were the Extension, with 4958 tons; Montana-Tonopah, 4581; North Star, 398; MacNamara, 2110; Merger, 585; and Midway, 150 tons. During the week ended January 17, 10 mines produced 10,297 tons of ore worth \$252,450. In the Extension mine the west shoot of the Murray vein at 950 ft. is 9 ft. wide, containing good ore. At 700 ft. in the Tonopah company's property, the Last Chance vein has widened from 2 to 3 ft. Three feet of good ore has been cut on the 665-ft. level of the Montana-Tonopah, this being the downward extension of the A. B. K. vein below the fault, which came in below 615 ft. On the 1100-ft. level of the Halifax, two veins are being developed, and the raise at 1000 ft. shows 10 ft. of ore. Three feet of ore is being driven on in the Midway at 635 ft. Cross-cutting north at 1166 ft. in the Mizpah Extension is still in favorable trachyte formation. The Buckeye-Belmont shaft is now in good condition to the 1000-ft. level. Pump stations will be cut at this and the 865-ft. level. A No. 5 Cameron pump is to be used in shaft-sinking. The shaft is in trachyte.

The Round Mountain company's superintendent, R. H. Ernest, states that the mine is improving. New ore-shoots have been cut at 450 ft. depth, 500 ft. southwest of the main workings on that level, and 100 ft. beyond this shoot the southwest cross-cut intersected another mineral zone. The first shoot is from 12 in. to 3 ft. wide over 250 ft., worth \$20 per ton, and the second is worth from \$3 to \$15 per ton. The

OREGON

JACKSON COUNTY

(Special Correspondence.)—M. Blanchin, president and general manager of the Bill Nye Corporation, a French company, but with American headquarters at San Francisco, arrived this week to make an inspection of the Bill Nye mine, near Gold Hill. M. Blanchin was pleased with the mine. It is now worked by one shift, but has been unwatered and overhauled, and the superintendent, Mr. Bellamy, states that an additional shift will soon be added. The new 75-ton mill at the Nellie Wright mine is nearly completed. It will be driven by electric power. The mine contains a large tonnage of ore. Gold Hill, January 15.

A. E. Smith, of San Francisco, has been visiting the hydraulic mines at Gold Hill, and has interested the miners in saving black sand, which contains platinum. Tacoma and Sutherlin, Oregon, people have purchased placer ground near Dowden Falls, three miles from Gold Hill. Active prospecting is under way. While there is plenty of water for large hydraulic mines, the smaller properties are short, the former depending on snow and the latter on local rainfall.

JOSEPHINE COUNTY

(Special Correspondence.)—A great amount of development is being done at the mines of Illinois valley, surrounding the pioneer camps of Kerby and Waldo. The hydraulic placers are making a fine showing, as the season is an excellent

one for surface mining. New workings have been opened on the Simmons-Cameron-Logan placers. A double-lift Hendy elevator has been installed on this line to take care of the tailing. John Logan, owner of the mine, is also operating the Osgood, nearby, with excellent results. The Wimer mine, known as the Deep Gravel, is operating this year under the management of Morrison brothers. A tubular elevator is also in operation on the Wimer, there not being sufficient natural dump to take care of the debris. The local manager, Mr. Wimer, reports that an exceptionally rich bank of pay-gravel is being worked this year. George W. Otterson, a prominent mining man of Ottawa, Canada, after making a thorough investigation of the mines of southern Oregon, took an option on a Grants Pass placer. He has begun work and will more extensively develop the mine, operating the present equipment during the remainder of the season.

Grant's Pass, January 15.

UTAH

CARBON COUNTY

About four miles from Helper is the Spring Cañon coal mine, which has a daily output of 1100 tons. The property has been producing only since March 1913, and the equipment is sufficient for a 2000-ton output. The mine is operated by electric power throughout. Two coal seams are being worked, 8 and 9 ft. thick, respectively. The town of Storrs is quite a model in every respect, and has a population of 500 to 600 people. Coal is shipped to California, Nevada, Idaho, Washington, Oregon, and Montana.

JUAB COUNTY

The Iron Blossom company has paid another dividend of \$100,000. The mine is in fine condition. The annual report of the Company shows net earnings of \$505,744 in 1913. The ore production was 39,526 tons, worth nearly \$20 per ton net. Ore reserves are 200,000 tons averaging \$20 per ton net. Ground north of No. 1 shaft of the Colorado mine has been leased. There is considerable activity in the north Tintic district. Ore shipments from 16 properties during the past week totaled 153 cars.

SALT LAKE COUNTY

The Utah Metal Mining Co. has issued a report covering the following work: On December 4, 1913, the Utah Copper Co. completed its pipe-line, and the water being supplied amounts to 440,000 gal. per day. Early in 1914 the flow from the springs on Middle cañon will be increased for the Utah company. The Bingham-New Haven Mining Co. is also supplied, and further water contracts are expected with other companies and the town of Bingham. Negotiations are under way for hauling waste and mill tailing through the tunnel to dump in Middle cañon. A drift is being driven west from the 9100-ft. point in the tunnel, toward the Bingham-New Haven property, the vein being 3 ft. wide in limestone. At 8600 ft. in the tunnel, 244 ft. of work has been done in favorable mineralized ground. It is hoped that the Company's finances will soon be on a sound basis.

WASHINGTON

PERRY COUNTY

J. L. Harper has forfeited his bond on the Surprise and adjoining mines, which includes the ground in dispute between the Republic Mines Corporation and the Quilp Gold Mining Co., and conceded to the latter under a written agreement by which the litigation was settled and the Quilp company came into unquestioned possession of the ground in dispute. The annual meeting of the Knob Hill Mining Co. was held at Spokane on January 14. During 1913 ore valued at \$140,000 was shipped from the mine, and \$25,000 was paid in dividends, the only Company in the state to pay any. Development at the mine is promising.

KING COUNTY

Gold receipts during 1913 at the United States Assay Office at Seattle showed a large increase over the previous year, being \$8,205,000, as against \$4,490,900 in 1912. The receipts from Alaska amounted to \$6,600,000. With the close of business January 1, 1914, the Seattle office had handled a total of 435 tons of gold valued at \$218,612,600 since its establishment in July 1898.

STEVENS COUNTY

The Silver Queen mine, two miles from Turk, which has been idle for 10 years, is to be unwatered and further development done. Rich silver ore was formerly mined. From the Providence, near the Silver Queen, ore was sent out last summer. It costs \$21 per ton to deliver ore to the Tacoma smelter from this district. Rich copper-silver ore has been opened in an abandoned adit of the Copper Queen claims, 9 miles from Chewelah. E. E. Thomason is the owner. No. 2 adit at the United Copper mine has been driven 3700 ft., leaving 500 ft. to reach the two-compartment winze sunk below the 600-ft. level. This should be through by April 1. The adit is 6 by 7½ ft., with a 0.5% grade, and a 30-in. gage track. Electric haulage will be used later on. The adit will have cost \$50,000 on completion. The mill has been increased by another unit of 12 stamps, the daily capacity being from 125 to 150 tons per day. From 80 to 100 men are steadily employed.

SPOKANE COUNTY

The following dividends have been paid by mining companies in the adjacent areas of British Columbia, Washington, and Idaho:

| Company. | 1913. | 1912. | Total to date. |
|--------------------|-------------|-------------|-------------------|
| B. C. Copper | \$ 88,756 | \$ 177,512 | \$ 704,155 |
| Bunker Hill | 817,500 | 752,100 | 14,729,250 |
| Can. Con. | 464,352 | 232,176 | 1,480,245 |

CANADA

BRITISH COLUMBIA

The Portland Canal company's adit is now in 2870 ft. At 2300 ft. No. 1 vein was cut, and is over 100 ft. wide, while at 2800 ft. No. 2 was cut, it being 40 ft. wide, mostly quartz. Neither vein was well mineralized where cut, but contained a little galena and pyrite. Drifts have been started north and south respectively on the two veins. The adit is being driven 60 ft. per week at a cost of \$20 per foot. W. J. Elmen-dorf is manager. Work has been resumed at the Glacier Creek mine, adjoining the Portland Canal property, on No. 1 vein cut in the latter. A shipment of ore from the Lake View mine, on Glacier creek, to the Tacoma smelter, yielded an average of gold, \$9.80; silver, 570.7 oz.; and lead 22.1%. A good tonnage has been opened in the mine. Complete returns for 1913 from the Grand Forks smelter of the Granby company are as follows: ore smelted, 1,246,013 tons, and blister copper, 21,960,997 lb. There was 17,434 tons of foreign ore treated. There is 16 in. of snow at the Hidden Creek property of the Granby company. A winze is being sunk from the 300 to 400-ft. level of the Jewel mine. C. A. Banks is manager.

The following table shows the estimated production of the principal properties in the Cobalt district in 1913 compared with 1912. The total for 1913 is estimated for the last month of the year, and in one or two instances for the last two and three months:

| Mine. | Gross ounces. | |
|-------------------------------|---------------|-----------|
| | 1913. | 1912. |
| Nipissing | 4,600,000 | 4,719,578 |
| Coniagas | 3,550,237 | 3,703,942 |
| La Rose | 2,623,000 | 2,920,344 |
| McKinley-Darragh | 2,250,000 | 2,704,868 |
| Buffalo | 2,000,000 | 1,890,150 |
| Kerr Lake | 2,109,975 | 1,895,309 |
| Crown Reserve | 1,833,333 | 2,714,766 |
| Cobalt Townsite | 1,783,554 | 1,505,396 |
| Cobalt Lake | 1,200,000 | 1,123,146 |
| O'Brien | 1,200,000 | 1,091,631 |
| Sen. Superior | 1,150,000 | |
| Beaver | 750,142 | 689,921 |
| Temiskaming | 735,000 | 1,242,243 |
| Temiskaming & Hudson Bay..... | 659,872 | 957,055 |
| Trethewey | 619,139 | 620,923 |
| Penn. Canadian | 365,000 | |

Dividends paid by Cobalt mines in 1913 were as follows, according to *The Daily Nugget*:

| Company. | 1913. | To date. |
|--------------------------------|-----------|------------|
| Beaver | \$ 60,000 | \$ 410,000 |
| Buffalo | 890,000 | 2,527,000 |
| Caribou-Cobalt | 25,000 | 25,000 |
| City of Cobalt | | 139,321 |
| Cobalt Central | | 192,845 |
| Cobalt Lake | 240,000 | 240,000 |
| Cobalt Silver Queen | | 315,000 |

| | | |
|--|--------------|--------------|
| Total | \$10,000,000 | \$46,935,718 |
| La Rose (shared privately previous to Nov. 1908) | | 1,204,862 |
| Private corporations (estimated) | | 3,500,000 |

Total

*The Hollinger is at Porcupine.

One from the Crown Reserve and Dominion Reduction companies, at Cobalt, was sent to Germany during the first week of January. During December the Dome mill at Porcupine treated 13,470 tons of ore yielding gold valued at \$106,904. This makes the total, since operation began in April 1913, 104,330 tons and \$936,106 in gold. The last ore shipment from the Tough Oakes at Kirkland Lake was 28 tons containing 23.59 oz. gold and 67.59 oz. silver per ton. Six shipments have made a total worth \$62,285.

Yukon.

All dredges of the Canadian Klondike Mining Co. are shut down for the winter. During the past season 6,263,515 cu. yd. of gravel was dredged, yielding 85,899 oz. gold worth \$1,331,000. Working expenses totaled \$480,000. Three boats with 16, and one with 71 cu. ft. buckets, were in operation. No. 2

dredge worked 268 days, a record for the district. They are all driven by electric power, generated by water-power from the Klondike river. J. W. Boyle, general manager, may probably install another boat at the upper end of the property in 1915. The hydraulic plants of the Yukon Gold Co. moved 2,875,000 cu. yd. of gravel during the season of 1913. Water for this purpose comes 75 miles, and was described in the *Mining and Scientific Press* of January 16 and 23, 1909, by T. A. Rickard. No. 6 dredge is to be re-erected in the spring on Gold Run creek, 50 miles from Dawson. No. 7 is to be transferred to 41 Hunker. Since starting dredging, the Company has completely worked out 108 full claims and several fractions. All boats are driven by electric power. During the season November 30, 1912, to December 1, 1913, the Klondike produced gold worth \$5,327,310, according to the report of George Black, territorial commissioner, published in the *Dawson Daily News*. The total for 1913 is estimated at \$5,500,000, an increase of \$500,000 over 1912. The gold output to date is \$174,652,411.

COLOMBIA

The Pato dredge recovered \$12,600 from 18,900 cu. yd. of gravel during the last week in December. November returns from the Colombian Mining & Exploration mine totaled \$22,000. Ten stamps are being erected in the new mill, and should be crushing soon.

KOREA

The Seoul Mining Co., operating the Suan concession, in Whang Hai province, Korea, reports the following results for December 1913.

| | |
|--------------------------|----------|

The Oriental Consolidated Co.'s December clean-up yielded \$143,000.

MEXICO

CHIHUAHUA

On January 15, 15,000 oz. of silver bullion from the Batopilas Mining Co. crossed the border at Nogales, Arizona, on its way to New York. Supplies are being sent to the mine for more active work.

JALISCO

On December 10, the Molokai 20 stamp mill of the El Favor Mining Co. started one treatment the entire plant from that date being available for El Favor ores. E. E. Bugbee, professor at the Massachusetts Institute of Technology, Boston, states that a preliminary test following magnetic separators, and the present cyanide process in use at El Favor, shows over 90% extraction from the manganese-silver ores of the Company's mines. There is on hand at the property 60 days supply of dynamite, 90 of cyanide, and large stock of other supplies. There have been no rebel disturbances in the district. On January 30 a dividend of 1¢ per share on 3,500,000 shares will be paid. At the beginning of 1914 the Company had \$54,195 credit in United States banks. Other receipts remitted since December 12 will add to this amount.

SONORA

About 75 men are working at La Colbriza mine, 20 miles south of Nogales, Arizona, on the border. The mine is now in full blast. A 100-ton mill will be built to concentrate low-grade ores.

COSTA RICA

The Abangarez Gold Field Co. report the following for November 1913. Ore treated, 7370 tons; total recovery by amalgamation and cyanidation, \$51,257; profit, \$2355; and improvements, \$1979.

Schools and Societies

COLUMBIA UNIVERSITY students numbering 502 earned a total of \$56,705 during their summer vacation last year.

The UNIVERSITY OF CALIFORNIA has started a course on oil production, including well drilling and handling of product.

The UNIVERSITY OF WASHINGTON, Seattle, opened a three months session for mining men on January 5. There were 44 registrations from 10 states, Alaska, and five foreign countries, to study quartz, placer, and coal mining.

The AMERICAN INSTITUTE OF MINING ENGINEERS will hold the 107th meeting in New York City on February 17 to 20. The committees on iron and steel, petroleum and gas, mining law, and mining geology have asked for a total of seven sessions for the reading and discussion of papers.

The New York section of the AMERICAN INSTITUTE OF MINING ENGINEERS held its last meeting on January 16. A paper on 'Mine Gases' was presented by N. H. Darton, of the U. S. Geological Survey. It covered the results of an exhaustive study made under the auspices of the U. S. Bureau of Mines.

The OLD FREIBERGERS society held their semi-annual dinner on December 4 at the Imperial restaurant, London, England. Sixteen members and one guest were present, and Edward Hooper, the president, occupied the chair. The evening was enlivened by the singing of old German Kommerslieder, and was thoroughly enjoyed by all those fortunate enough to be present.

The COLORADO SCIENTIFIC SOCIETY has elected the following members to serve during 1914: President, Richard A. Parker; first vice-president, E. N. Hawkins; second vice-president, Thomas B. Stearns; treasurer, J. W. Richards; secretary, H. C. Parmelee; executive committee, J. D. Skinner and Charles A. Chase, term expiring January 1, 1917; and Victor G. Hills to fill vacancy expiring January 1, 1916.

The OLD FREIBERGERS in America held their regular annual meeting at the Hofbräu Haus, New York City, on December 20. A pleasant evening was spent around the festive board. All the former officers were reelected, namely, Dr. R. W. Raymond, president; Gardner F. Williams, vice-president, and C. L. Bryden, secretary and treasurer. It was decided to hold a meeting in San Francisco in 1915 during the Panama-Pacific Exposition, and a number of the members are planning to go to Freiberg in 1916, to help celebrate the 150th anniversary of the founding of the old Bergakademie.

The annual meeting of the FARADAY SOCIETY was held on November 26, 1913, at the Institution of Electrical Engineers, London. The following officers and council were elected to serve for the year 1913-14: president, Sir Robert Hadfield; vice-presidents, G. T. Beilby, K. Birkeland, W. R. Bousfield, Bertram Hopkinson, A. K. Huntington, T. Martin Lowry, Alexander Siemens; treasurer, F. Mollwo Perkin; council, R. Belfield, H. Borns, W. R. Cooper, F. G. Donnan, Emil Hatschek, R. S. Hutton, Alfred W. Porter, E. H. Rayner, R. Seligman, and Maurice Solomon. The seventieth ordinary meeting was held afterward. Ernest Vanstone submitted a paper on 'The Electrical Conductivities of Sodium Amalgamates.' This discussion is a preliminary to a more extensive investigation. A paper on 'The Influence of a Second Solute on the Solubility of Orthophthalic Acid,' was read by A. C. Rivett and E. I. Rosenblum. T. Martin Lowry showed a series of photographs illustrating the formation of an oxidizable variety of nitrogen, by the action of a spark discharge on air at atmospheric pressure. There was a discussion on the paper previously presented by F. J. Brisleon, 'The Density of Aluminum.' J. W. Richards, of Lehigh University, had also previously sent a note on 'Over-voltage,' which was discussed.

Personal

J. A. AGNEW sailed from Nicaragua Tuesday.

W. Y. WESTERVELT is at Redlands, California.

H. S. BRUCKUNIER was in San Francisco last week.

A. W. ALLEN expects to return to England in April.

J. W. FINCH has returned to Denver from California.

J. V. N. DORR has returned to New York from Cobalt, Canada.

GEORGE E. FARISH has returned to New York from Cobalt, Canada.

ROSS B. HOFFMANN and JACK HOFFMANN have gone to London.

C. E. BUNKER has gone to Nicaragua to become manager at La Leonesa gold mines.

RALPH ARNOLD will deliver a course of lectures at the University of Chicago this spring.

J. M. LOVEJOY is now superintendent of the Minas San Juan, Huantajaya (via Iquique), Chile.

J. H. COLLIER has returned from Nicaragua, where he has been investigating metallurgical problems.

W. S. HARRISON, general manager for the San Francisco Mines of Mexico, of Rugby, England, is at El Paso, Texas.

FRANK LANGFORD has left India for the Malay States and will return from there to the United States by way of the Philippine Islands.

HENRY H. ARMSTEAD sailed from Vera Cruz January 8 for New York, where he will remain until the last of March, at which time he will return to Mexico.

NORVAL J. E. WELSH has withdrawn from the management of the Otero Copper Co., at Orogrande, New Mexico, and is now at Organ, Dona Ana county, New Mexico.

GEORGE A. CAMPHUIS and GERALD RIVES have formed a partnership in mining engineering and mine management work, with headquarters in the Mills building, El Paso, Texas.

GODFREY E. MORGANS passed through New York on his return to London from Colombia, where he has been examining large coal and iron properties for Colombian investors.

S. WOLFF, formerly manager of the Cleveland office of the Allis-Chalmers Manufacturing Co., has been appointed Chicago manager for the De Laval Steam Turbine Co., with offices in the Peoples Gas building.

Among those present at the meeting of the Geological Society of America, at Princeton, December 30 to January 1, were C. D. WALCOTT, G. O. SMITH, J. F. KEMP, A. H. BROOKS, J. M. CLARKE, W. H. HOBBS, WILLET G. MILLER, A. P. COLEMAN, J. A. DRESSER, C. A. FISHER, N. H. WINCHELL, F. D. ADAMS, C. A. DAVIS, F. H. KNOWLTON, G. H. ASHLEY, A. W. GRABAU, MELVILLE E. STONE, T. W. VAUGHAN, I. C. WHITE, U. S. GRANT, ELLSWORTH HUNTINGTON, W. J. MILLER, S. W. BEYER, H. A. BUEHLER, E. O. HOVEY, HEINRICH RIES, FRED E. WRIGHT, E. H. KRAUS, GILBERT VAN INGEN, SIDNEY PAIGE, H. L. FAIRCHILD, J. VOLNEY LEWIS, THOS. C. BROWN, D. W. JOHNSON, J. W. SPENCER, A. L. DAY, LAWRENCE MARTIN, F. R. VAN HORN, R. VAN A. MILLS, A. C. BOYLE, T. T. READ, and G. P. MERRILL.

Obituary

Death of THEODOSIE TCHERNYCHEFF, director of the Geological Survey of Russia, is announced by cable. Tchernycheff was an able geologist and an experienced administrator well known to many Americans to whom he had extended courtesies in his own country. He was one of the leaders of the International Geological Congress and a man of first rank in his profession.

The Metal Markets

LOCAL METAL PRICES

| Zinc dust, 100 kg. zinc-lined cases, 7 1/4 to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York)

NEW YORK, January 21.—A change for the better is to be noted in the copper market, its position is at present strong and a good demand for export is being experienced. Standard spot to April is offered at 14.50 and electrolytic is quoted at from 14.50 to 14.62 1/2. Lake copper is quoted at 15. Copper securities in general showed an advance during the day. The lead market is firm but quiet, with quotations at from 4.05 to 4.10. Spelter is also quiet. Gold bars to the value of \$2,000,000 have been engaged for shipment to Paris, making a total of \$4,000,000 for this present movement of bullion. The London market is cabled as firmer, with an upward tendency in mining shares.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

To those who follow the course of the silver market there has been much of interest in the past year. Among the most important events may be mentioned the successful issue of the \$10,000,000 loan, the suspension of the Indian Specie Bank, with the collapse of the native group of speculators, who have influenced the market for so long, and further important purchases of silver by the Indian Government. In addition, there has been political unrest both in Mexico, the largest producer of silver in the world after the United States, and also in China, the only important country which still maintains a silver currency, and which, in consequence, is one of the largest users of the metal. As a result the market has been an irregular one and difficult to forecast, according to Pixley and Abell's annual survey. India, with its immense population, has again been the dominating factor in the market. The Government has purchased during the year about \$5,500,000 of silver for coinage into rupees. A report on Indian finance is expected during the current month. China has been fairly quiet during 1913. Stocks of silver in Shanghai are \$5,785,000, as against \$3,347,000 in 1912. Imports of silver into England in 1913 were \$14,520,000, of which \$13,260,000 came from the United States, Mexico, and Canada. Shipments from San Francisco totaled \$2,348,000. Exports from England in 1913 were \$15,326,000 in silver bullion and coin, of which \$9,850,000 went to India. Stocks in London are \$1,000,000.

| June | 17.23 | 14.71 | 17.37 | 14.23 |

The New York copper market last week may perhaps be best described as hopeful, and a gradual improvement was evident. There was some quiet buying during the week at slightly improving prices, and the receipt of foreign statistics showed a big decrease in visible supplies in Europe during the first half of January, and will probably soon be reflected in better prices and increased buying on foreign account. The foreign visible supply in England, France, and afloat thereto, on January 15 had decreased 1892 tons in the fortnight to 19142 tons. An increase of 240 tons, on the other hand, was shown at European warehouse points, including Hamburg, Rotterdam, and Bremen, the supplies there now being 8755 tons. Hamburg showed an increase of 302 tons, Bremen stocks dropped 62 tons, while those at Rotterdam were unchanged. This presumes, of course, that there is nothing in the allegation that large foreign shipments have been made on consignment. Exports from January 1 to 15 were 16395 tons, as compared with 17001 tons in the same period last year.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed on the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 15 lb., are given below:

| Week ending | | Jan. 8 | | 1913 | |
|------------------|---------|--------|-------|-------|-------|
| Dec. 24 | per lb. | 39.50 | | | |
| " 31 | per lb. | 39.00 | | | |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Monthly averages. | | | | | |
|-------------------|-------|-------|------------|-------|-------|
| | 1912. | 1913. | | 1912. | 1913. |
| Jan. | 42.53 | 50.45 | July | 44.25 | 40.70 |
| Feb. | 42.96 | 49.07 | Aug. | 45.80 | 41.75 |
| Mch. | 42.58 | 46.95 | Sept. | 48.64 | 42.45 |
| Apr. | 43.92 | 49.00 | Oct. | 50.01 | 40.61 |
| May | 46.05 | 49.10 | Nov. | 49.92 | 39.77 |
| June | 45.76 | 45.10 | Dec. | 49.80 | 37.57 |

On January 22 the prices for tin were firm and quotations as follows: Spot for February, 38.75 to 39; March, 38.80 to 39.10; and April, 38.85 to 39.25c. per pound.

Mineral Production of British Columbia

The following figures are from the preliminary review of the province in 1913 by the mineralogist, William Fleet

| Mineral. | Quantity. | Value. | Increase or decrease. |
|------------------------------|------------|-----------|-----------------------|
| Gold, placer, ounces..... | | \$540,000 | — \$15,500 |
| Gold, lode, ounces..... | 266,547 | 5,509,526 | — 187,084 |
| Silver, ounces..... | 3,569,642 | 2,027,557 | — 217,512 |
| Lead, pounds..... | 54,205,594 | 2,130,280 | — 324,653 |
| Copper, pounds..... | 46,042,379 | 7,021,463 | — 1,387,050 |
| Zinc, pounds..... | 7,100,000 | 340,800 | — 24,661 |
| Coal, long tons..... | 2,136,694 | 7,478,429 | — 1,722,385 |
| Coke, long tons..... | 285,123 | 1,710,738 | — 124,740 |
| Building materials, etc..... | | 3,400,000 | — 35,722 |

Total..... \$30,158,793 — \$2,282,007

Practically all the placer gold is obtained in the Cariboo and Cassiar districts, the latter including Atlin. The lode-gold districts are Rossland, 135,300 oz.; Boundary, 103,300 oz., including Camp Hedley with 38,300 oz.; Nelson, 23,500 oz.; Coast, 3000 oz.; and Lillooet, 1300 oz. Silver was produced by the Slocan district, with 1,860,000 oz.; Ainsworth, 487,000 oz.; East Kootenay, 413,000 oz.; Boundary, 380,000 oz.; and Nelson, 160,000 oz. Slocan and Ainsworth were responsible for 31,000,000 lb. of lead; East Kootenay, 20,300,000 lb.; and Nelson, about 2,000,000 lb. A small bounty was paid to lead producers during part of the year. Copper amounting to 29,000,000 lb. came from the Boundary, chiefly Granby; 14,000,000 lb. from the Coast; and 2,200,000 lb. from Rossland. Slocan produced nearly all of the zinc. Laboratory experiments, in electric smelting lead-zinc ores, made by the Dominion Department of Mines, have reached an advanced stage, and an electric furnace has been constructed at Nelson, with G. C. Mackenzie in charge. Slocan ores are being experimented with for their commercial reduction. Labor troubles on Vancouver island caused a decrease in the coal output of the province. The Island mines produced 962,620 tons; Nicola, 262,768 tons; and Crowsnest, 1,351,498 tons.

Gold Movements in England in 1913

Imports were as follows, according to Pixley and Abell: Australia, £452,000; Brazil, £472,000; British India, £2,345,000; Java, £336,000; South Africa, £40,798,000; and West Africa, £1,596,000.

Exports were as follows: British India, £9,955,000; France, £1,831,000; Germany, £8,824,000; Holland, £96,000; Russia, £2,080,000; Switzerland, £442,000; Turkey, £401,000; and United States, £600,000.

Company Reports

TONGKAH HARBOUR TIN DREDGING COMPANY

As its name implies, this Company operates dredges in a harbor in Siam. The report covers the seventh year of work, and shows the following:

| | |
|--|-----------|
| Harbor gravels dredged, cubic yards..... | 3,336,190 |
| Yield of tin oxide, tons..... | 1,339 |
| Yield per cubic yard, pounds | 0.90 |
| Value per cubic yard, cents | 23 |
| Cost of dredging, cents | 7.6 |
| Other costs, cents | 1.4 |
| Value of output | \$758,000 |
| Profit | 385,000 |
| Dividends paid | 288,000 |
| Surplus | 337,000 |

No. 6 dredge is being built in Scotland by W. Simons & Co. It will have a digging capacity of 60 ft., and is to cost \$124,800. Only \$49,000 has now to be paid to the Government of Siam. Eliot T. Lewis is general manager.

CONIAGAS MINES, LIMITED

This Company operates at Cobalt, Ontario, and the report covers the year ended October 31, 1913. Development work during the year has been mostly on No. 9, 12, 18, and 28 veins, and cross-cutting to the southern boundary. There has also been considerable development done on small veins on No. 1 level. On account of recent discoveries in the claim adjoining the southern boundary, it is necessary to operate from No. 4 shaft, which was sunk in 1907-1908 near the southern boundary of the claim. A shaft-house will be erected and operations started within a few weeks. Broken ore in stopes has increased 14,000 tons. Ore reserves are as follows: 3870 tons containing 11,610,000 oz. silver, 132,525 tons with 2,650,000 oz., 52,130 tons with 2,085,200 oz., and 10,500 tons with 315,000 oz., a total of 16,660,700 oz. Allowing for contingencies, this should be reduced to 13,329,000 oz. New orebodies opened contain 2,950,000 oz. The mill operated 98% of the possible time, and treated 54,890 tons of ore. This, with concentrate shipments, yielded a total of 3,572,399 oz. Since 1905 the output has been 17,662,904 oz. of silver.

ST. JOHN DEL REY MINING CO., LTD.

The fifty-fifth half-yearly report of this Company, which operates a gold mine in Brazil, contains the following information from G. Chalmers, the superintendent: The ore reserves, down to and including horizon 18, a total depth of 983 ft. vertical, amounts to a total of 1,045,912 tons. This is equal to 5½ years supply at 192,000 tons per year. Development covered 1345 ft., and at horizon 18 the lode has been opened 259 and 222 ft. east and west, respectively. There was 70,070 tons of filling put into the mine. During the term the Sirocco fan ran with only two stoppages totaling 3 hours 50 minutes, consequently ventilation was good throughout the workings. The electric locomotives did excellent work. A total of 167 accidents occurred in the mine, of which 7 were fatal, 5 being due to carelessness of a hoisting engineer, 1 being probable suicide, and the last due to a man trying to get off a cage while in motion. The labor situation has been serious, but is improving by the importation of Japanese, 107 coming during the half-year. It is hoped that they will prove to be efficient. The various plants have worked well. Two new Chalmers & Williams tube-mills have been erected. Manganese steel linings are much preferable to the chilled iron make. From two quarries, 1391 tons of hard rock was excavated and sent to the mill for use in tube-mills. The sand-settling system has been al-

tered to cope with a larger tonnage, and the filter plant requires extending. The Edwards furnace treated 2610 tons of sand, yielding gold worth \$9600. The 120-stamp mill worked 138.3 days, and 82,500 tons of ore was treated yielding \$950,000. Extraction was 92.63%. The profit amounted to \$259,000. On December 19, 1913, dividends amounting to \$120,000 were paid on the 10% preference and ordinary shares. Mortgage bonds outstanding amount to \$134,000, and investments on the reserve fund are \$460,000. The rainfall was 11.07 in., or 4.05 in. less than during the previous period. The Morro Velho and Raposos tramway is of great service, and 14,588 passengers were carried. Health of the camp has been good, there being only four cases of typhus fever. The Hotel Retiro shows a loss on operation for the half-year. Brazilian exchange on the Company's drafts averaged 32.19 per milreis.

MEXICAN GOLD AND SILVER MINING COMPANY

The fiscal year of this Comstock company ended on October 31, 1913, and Whitman Symmes, the superintendent, gives the following information: At the date of the last report the stopes above the 2300-ft. level had been practically worked out, and extraction was continued from the 2400 and 2500-ft. level stopes. The last ore from the 2300-ft. stope was taken out on January 17. The 2400-ft. stope was worked by the shrinkage method, which avoided the use of any considerable amount of timber. When the work was completed, the ore was drawn from the stope, and it was allowed to cave, according to the usual practice in such methods. The last ore was taken out on February 28. In April the 2500-ft. stope was nearly exhausted, and ore was taken from beneath the sill floor of the stope on that level. By May 9 all the ore below the sill floor that appeared to be of value was taken out, and on May 16 all ore was removed from the main 2500-ft. stope. This stope was worked by the square-set system of timbering. The extraction of ore from the mine during the past year has been as follows:

| Level, ft. | Tons. | Gross yield. |
|-------------|--------|--------------|
| 2300 | 202 | \$ 3,139 |
| 2400 | 7,652 | 142,721 |
| 2500 | 6,318 | 260,163 |
| Total | 14,172 | \$406,023 |

During the previous term an incline winze was being sunk below 2500 ft., and at February 14 it was down 147 ft. in practically barren rock. No arrangements being made with the Comstock Pumping Association, the work was abandoned. There being no further work that could be profitably done in the Mexican mine until the water-level had been lowered, all equipment was removed from below 2000 ft., and the drifts and air-ways securely timbered. Ore from the Mexican mine and surface dump milled during the past year, was 15,973 tons, yielding \$462,434. Mining and treatment, etc., for the Mexican totaled \$10.40 per ton.

An option on the Comstock Quartz Mining Co.'s property was allowed to expire, as prospecting did not open anything of value. The Mexican company has a 60% interest in the Monte Cristo lease, and the mill treated 13,274 tons, yielding \$109,071, also 118 tons of concentrate yielding \$5299. The cost of this treatment was \$2.83 per ton. In the Monte Cristo mine, work is under way on the 350-ft. level. When a satisfactory agreement has been made with the Pumping Association and adjoining mining companies, the lower levels of the Mexican mine will be explored.

The total value of the bullion from all sources was \$564,258, of which \$49,889 was from the Mexican and \$114,379 from the Monte Cristo. Operating expenses were \$177,570; construction, \$27,891; and miscellaneous, \$26,267. Value of supplies at the end of the year, October 31, 1913, was \$14,917; balance from Monte Cristo company, \$45,012, and cash at San Francisco and Virginia City, \$253,922. The Company has since decided to invest \$145,000 at Rochester, Nevada.

Horizontal Duplex Power Pumps for High Efficiency

A notable installation of pumps which was recently put into successful and continuous operation is that furnished to the Santa Gertrudis at Pachuca, Mexico, by the Fred M. Prescott Steam Pump Co., of Milwaukee. The original specifications issued by the purchaser called for vertical quintuplex plunger pumps, but after a full consideration of the accessibility and durability of the two designs, as well as the high economy of the horizontal duplex, the latter pattern was selected. The manufacturers have kindly furnished the following information regarding the plant.

There are three pumps of the same size in an underground station. Each has 4½-in. plunger diameter and 36-in. stroke, and a capacity of 500 gal. per minute against 1500-ft. head at 47 revolutions. The pumps handle mine water and are placed so as to permit putting in a fourth unit if the water increases beyond that which can be handled safely by two. The third pump is used as a spare. The electric motors driving the pumps are alternating-current induction motors of 500 r.p.m. synchronous speed, 3-phase, 50-cycle current.

HORIZONTAL DUPLEX PUMP.

The illustration, taken from a photograph of these pumps, will give a good idea of their general appearance, and especial attention is directed to the design of the water end. The variation in the water flow made it desirable that some means be provided for changing the capacity, and this is accomplished in this design by changing diameters of plungers, which is made possible by the use of a hollow steel cross-head admitting of plungers being removed and others substituted without dismantling or moving any of the permanent parts of the pump and within a very short space of time. Further, all dripping of water on the main slides is done away with, by having the stuffing-boxes centrally placed instead of at the ends. The water valves are of the double port design and faced with steel, and the valve pots are fitted with hinged covers to provide for quick inspection and repair. The water ends are furnished with both suction and discharge air-chambers of ample capacity, as well as an air-charging device which is operated in connection with the compressed air supply in the mine together with the pressure from the discharge column. Ample and removable stuffing-boxes and glands are provided at the inboard ends of the water barrels. The power end is of the heavy tandem type, the same as is used in connection with the Corliss fly-wheel pumping engines built by the Fred M. Prescott Steam Pump Co., and proportions are ample for any strain incident to mine work. The main bearings are of the quarter-box type, and all pins, rods, cranks, and shaft are of heavy design and section and the best construction. The gears employed on this work are of the cast steel 'herringbone' type in bolted halves, with pinions cut from solid blanks. The couplings joining the motor and pinion shafts are of special

design with leather links taking up any slight inaccuracies of alignment and operation. A mechanical efficiency of 85% was guaranteed on these pumps and their gears, which efficiency is reported to have been exceeded in actual work. These units are, for the horse-power developed, very compact, yet heavy, and sectionalized so as to go down any ordinary mine shaft.

Catalogues Received

T. H. PROSKE, Denver, Colorado. Booklet. 'The Imperial Drill Sharpening Machine.' 15 pages. 5 by 7 inches. Illustrated.

ELECTRIC WEIGHING Co., New York. Booklet. 'Electric Conveyor Scales.' Messiter patents. 8 pages. 6 by 9 inches. Illustrated.

RIX COMPRESSED AIR & DRILL Co., San Francisco. Leaflet. 'Portable Drilling Outfits. Self Rotating Air Hammer Drills.' 4 pages. 7¼ by 7¼ inches. Illustrated.

JUSTRITE MANUFACTURING Co., Chicago, Illinois. Booklets. 'The Justrite Carbon Lamps and Lantern,' and 'The Justrite Carbide Half-Shift-Lamp.' 10 pages. 3½ by 6¼ inches. Illustrated.

NATIONAL TUBE Co., Pittsburgh, Pennsylvania. Leaflet. 'Safety Calendar.' 8½ by 11 inches. Illustrated. Issued for the Company's employees, in connection with the 'safety first' trend in factories.

THE CYANIDE PLANT SUPPLY Co., 1 Broad Street Place, London, E. C. 'Tube-Mills.' Supplement No. 27. 48 pages. 6 by 8 inches. Illustrated. Descriptions are given of sectionalized mills, mills at various reduction plants, directions of driving pulleys, and standard specifications of tube-mills.

BUFF & BUFF MANUFACTURING Co., Boston, Massachusetts. Booklet. 'The Buff Transit.' 32 pages. 4 by 6 inches. Illustrated. Index. This surveying instrument is the result of 58 years of study. It has a 12-in. telescope with a power of 26.5 diameters. Full details are given as to its construction.

THE COMMONWEALTH GAS POWER Co., LTD., Hoskins Foundry, Perth, Western Australia. Booklet. 'The Commonwealth Down-Draught Generator.' 5½ by 8 inches. Illustrated. This apparatus is used in connection with suction-gas engines, and is a new system of generation where any kind of wood or refuse is consumed. In Australia, the generator and many makes of engines are working with great success. The cost of fuel being 0.32 cents per brake horse-power.

THE LUNKENHEIMER Co., Cincinnati, Ohio. Catalogue. 'An Improved Automatic Injector.' This injector is exceptionally durable, efficient, and economical. The tubes, which parts are subjected to the greatest wear, are made of a special bronze composition of extreme hardness, and the injector can be subjected to long and severe usage before any sign of wear on the tubes appears. A feature of great importance is the scientific design of the tubes, which aids in prolonging their efficiency, even after considerable wear takes place within them. After the tubes are worn to such an extent that the efficiency of the injector is lost, new tubes can be quickly and easily inserted at small cost. The Lunkenheimer

AUTOMATIC INJECTOR.

injector is automatic at all times, and will restart at once after a temporary stoppage of steam or water supply.

JAPANESE mineral production showed an increase in 1913, and final figures are expected to show a total value of over \$70,000,000 as compared with \$65,000,000 in 1912. The copper output amounted to 154,000,000 pounds.

THE review number of the *Bonanza* states that in the early days of Tonopah, the weekly supplies included four barrels of spirits frumentum; but even with such a bad beginning the camp has flourished like the green bay. Perhaps the 'spirits' was of the same brand as that which Lincoln once inquired for that he might send a barrel to each of the federal generals.

ANTHRACITE production of Pennsylvania for the year 1913, according to figures collected by the producers, amounted to 69,069,628 tons, which is an increase of 5,459,050 tons over that of the preceding year, but 884,669 tons less than the 1911 production. While the exhaustion of these fields is periodically predicted at a not far distant date, indications are that Pennsylvania will supply anthracite for many years to come.

THE mining department of the Auckland Exposition, which is now open and continues until the first of May, contains many interesting features. Mineral collections and working models, showing the ancient and modern methods of mining and ore treatment employed in New Zealand and which account for the production of £82,000,000 in gold from the native ores, are exhibited, and a comprehensive survey of the local mining industry is attractively presented.

LEACHING experiments on the Nevada-Douglas copper ores, which are being conducted at Denver, are reported as having demonstrated that copper can be produced by this method at the mine at a maximum cost of between 8 and 9 cents per pound, this charge including mining, crushing, sulphuric acid consumption, and all other charges incidental to the treatment of ores. Copper produced by this method, it is claimed, is as good as the best electrolytic copper. It is hoped that from the introduction of sulphur dioxide gas into the lixiviant for the purpose of reducing the ferric salts to the ferrous condition an improvement in efficiency will result, and experiments toward this end will be conducted.

CALIFORNIANS and others interested in recent changes of law as relates to the mining industry of the state will welcome Bulletin 66 of the State Mining Bureau, which is available for distribution free. In it will be found a summary of changes in the United States and California statutes in 1913, and of recent court decisions of local importance.

GOLD AND SILVER are articles of commerce as well as media of exchange, and the world movements of the surplus production of each year are matters of first moment to miners and merchants. We print elsewhere a long abstract of the annual bullion letter of Messrs. Samuel Montagu & Company which throws many sidelights upon the demand for the precious metals.

TEXAS has modified its mining law, a recent enactment of the legislature providing that the Land Commission may issue a permit for prospecting for mineral to any applicant upon the payment of 10 cents per acre for the land upon which he intends to prospect. When minerals in paying quantities are found, the applicant has the right to lease the land for a period of ten years. Each applicant is restricted to 1280 acres, but when such land is situated within 10 miles of any producing mine or a well of oil or gas, the number of acres that may be awarded is restricted to 200.

MINERAL exports for the month of September from Mexico, according to the recently published official statistics, have shown a decided decline from that of the same month of the previous year. The total gold exportation during the month amounted to \$2,692,132, which is a decline of \$703,948. The silver exports for the month totaled \$4,740,031, which is a decline of \$6,087,472 from that of the same month of the preceding year. Copper exported amounted to \$893,544, which is a decline of \$1,306,493 for the same period. Petroleum has shown a material increase in exports amounting to \$1,787,515, which is an increase of \$1,132,157.

EXTENSIVE deposits of platinum are reported as having been discovered at Wenden, in Westphalia, a district which has been the producer of iron, lead, copper, and zinc in the past. In that the platinum occurs as an alloy with silver, its presence had not been suspected as in this alloyed form it was soluble in nitric acid and being in solution as a nitrate it had not been previously tested for. The discovery in Westphalia is reported as the result of the chemical analysis of bore-hole samples. The platinum is contained in a rock formation overlying the common-metal orebodies. Assays from nine holes over an area of 500 acres show ore carrying from 0.9 to 1.9 ounces of platinum per cubic yard. These results are higher than obtained from the Ural deposits and preparations are being made for mining this orebody. In that the

production last year was only 1,304 tons, valued at \$1,732,200, and the visible sources are fast diminishing, this field, if it prove as good as anticipated, will be a welcome addition to the world's resources.

STRIKES seem still to occur, however much the laws be tinkered, and experience still holds first place as schoolmaster. The general strike in New Zealand, called three months ago, has now been declared off and the thousands of miners and union men who responded to the exhortations of the labor agitators have returned to work with nothing gained save an experience, which may or may not prove profitable in the future. It will be recalled that the New Zealand parliament has enacted a law for the compulsory arbitration of labor disputes, but this proved futile in the present instance, and settlement has only been brought about through pressure by law-abiding citizens who refused to allow the strikers to interfere with those who desired to work. The situation is similar to that in the Lake Superior copper region where present indications point to a like solution. The recent government investigation in the latter case seems to have resulted in nothing more tangible than a report that some of the smaller companies were operating at a loss, while the Calumet & Hecla company has made "extremely large profits." The conciliators' report has been rejected by the operators on the ground that they will have no dealings with the Western Federation of Miners, nor would they have any of its members in their employ.

IT is a pleasure to print, as we do this week, a clear and authoritative statement regarding the plans for a California mining exhibit at the Panama-Pacific Exposition. Mr. van Barneveld's argument for a consolidated exhibit centrally placed, is unanswerable. To hold an exposition in California without such an exhibit of the industry which made California famous, would be as disappointing as to open a mine that contained no ore—if Mr. Rickard will pardon the metaphor. The artist's sketch that has been prepared and copies of which are furnished with this issue, shows what a striking picture of California's great industry is possible, and anything less than the best would here be a failure. The state as such has appropriated no money for exhibits. This is a radical departure from previous custom. We believe it to be a mistaken policy that may lose to California much of the benefit that would otherwise flow from the exposition. No possible series of county exhibits can make up for the absence of suitable collections representing, not the resources, but the industries of the state. If this mistake is to be rectified it must be through the overruling good sense of those in charge of the county exhibits, and we are glad to say that there is a general disposition to make up in this way for the failure of the state administration to appreciate its opportunities and responsibilities. California must have an exhibit of gold mining, and Mr. van Barneveld has proposed the only feasible plan.

Metal Mine Accidents

Statistics of the metal mine accidents in the United States during the year 1912, compiled by Mr. Albert H. Fay and recently published by the Bureau of Mines, seem to be indicative of the success of the 'Safety First' movement. It is an encouraging and hopeful sign to find that there was a decrease in the number of fatalities in metal mines in 1912 as compared with the previous year, although this decrease amounted to only 5 per cent. During 1912 the number of men killed in and about metal mines in the United States was 661, compared with 695 killed in 1911, so we may consider that 34 human lives were saved. This saving of life is well worth while, but the number of fatalities and accidents is still appallingly large. Mine operators, however, have awakened to the necessity for keeping their workings in better condition and providing more adequate safety appliances, so it is hoped that there will be a gradually diminishing death list in the future. In many states the enactment of rather drastic workmen's compensation laws has forced operators to adopt elaborate precautionary measures, but a large number of mine managers have voluntarily provided better facilities for guarding the lives of their employees since they have found this to be wise from a purely economic standpoint. Mr. H. C. Hoover informs us that in Australia large sums of money have been spent to make the mines absolutely safe, and that these expenditures have invariably proved to be good business investments, resulting in increased efficiency and lower costs per ton of ore mined. The same result has followed from expenditures by the United States Steel Corporation and other American concerns.

An analysis of Mr. Fay's report reveals a number of interesting facts. During the year 1912 the total number of men killed in and about coal mines was 2360, out of 722,662 men employed, or at the rate of 3.27 per thousand. Of the 169,199 men employed in and about the metal mines of the country, 661 were killed, this being at the rate of 3.91 per thousand men employed. Among the metal mines the fatalities were greatest in the copper properties, where the rate was 4.62 killed and 34.90 seriously injured per thousand. The fatalities in the gold, silver, and miscellaneous metal mines were 3.99, and the serious injuries 13.89 per thousand. Statistics of the iron mines show that 3.76 men were killed and 39.35 seriously injured per thousand. In the lead and zinc mines of the Mississippi Valley, there were 3.77 fatalities and 10.26 serious injuries per thousand men employed. In other mines, such as asbestos, asphaltum, graphite, kaolin, phosphate, and salt properties, the rate was 1.52 killed and 10.23 seriously injured per thousand. This low rate may be due in part to the fact that accurate records are seldom kept in these mines.

An instructive comparison is made between the number of accidents in metal mines and those in coal

mines. Although the apparent fatality rate in 1912 was higher in metal mines than in coal properties, the comparison is not just, because, although the metal miners worked 287 days during the year, the coal miners worked but 225 days. Using a 300-day year as a basis, and reducing the figures from both the metal and coal mines to a common denominator, the average fatality rate for all of the metal mines becomes 4.09, and that for the coal mines 4.36 per thousand. On this basis, therefore, the fatality rate in coal mines is actually the higher.

The effect of careful management and systematic efforts to decrease the number of accidents on the part of the larger mining companies has been a material lowering of the fatality rate in the large mines as compared with small properties and prospects. In the case of the small mines the average number of days worked was only 105 for the year, compared with 305 days for the copper mines and 277 days for the gold and miscellaneous metal mines. On the basis of a year of 300 working days, the fatality rate in mines where less than 1000 days' work was performed during the year was 7.05, and that for mines with more than 1000 days' work was 4.02 per thousand. The fatalities in and about prospects and small mines were chiefly due to the careless handling of explosives, and secondarily to shaft accidents. The more careful supervision and regulation of the larger properties is evidenced by the smaller number of accidents caused by explosives, but there is marked lack of adequate provision against falls of rock in the mine workings. In the large mines deaths and serious accidents were caused primarily through poor stoping methods and inadequate timbering or filling of the workings. Of the fatalities, 34.52 per cent was caused by falls of rock; 22.55 per cent by falling down shafts, winzes, and stopes; 14.21 per cent by explosives, and 9.99 per cent was due to tramming and haulage systems. These figures show that the necessity for better methods of stoping and timbering, and more effective safeguards around shafts and winzes, is most imperative. It too often happens that in the endeavor to mine ore cheaply and quickly the condition of the mine workings is almost entirely disregarded until calamitous falls of rock have taken place.

What Is the Matter With Prospecting?

The series of letters upon this subject that we have been printing have proved distinctly worth while. They have been widely quoted and commented upon, and we can not but feel that they have helped to clear the air. They have punctured some fallacies and discouraged some hopes, but they have brought us all face to face with actual conditions, and that is always a prerequisite to progress. We are grateful to our friends for their generous response to our request for information, and we sincerely trust that in this case the bread cast on the waters may return to them after

the cost of living has gone up.

Summarizing the letters, of which the last are printed this week, it may be said that there is great unanimity with respect to the question of the availability of adequate amounts of money for finding and developing prospects. Almost without exception, it is agreed that there is plenty of money for the purpose, although at the present time there may be less than usual on account of the general depression in business circles. The reasons given for the apparent lack of interest in the mining industry as far as the search for and development of new mining camps is concerned, are numerous and varied. On one point there is general agreement, and that is the fact that this country has been so thoroughly explored that almost all of the orebodies which could easily be seen and recognized have already been discovered. Now that the entire country is fairly well settled, the *terra incognita* no longer exists and the spirit of adventure no longer stimulates. At the present time the old-fashioned prospector has almost ceased to exist, for his chances of 'striking it rich' are so remote that he has turned from the hardships of exploration to the comforts afforded by the large mining camps. Inasmuch as there have been no discoveries of moment in the past few years, there is no encouragement to grubstake and send out prospecting parties, although plenty of money is available for that purpose. In other words, funds for prospecting purposes now appear to be less plentiful than they formerly were, only because the chance of finding profitable mines has greatly diminished. In sparsely settled regions, like Alaska, and parts of Mexico and South America, where it may still be possible to obtain large rewards for the hardships endured, the old type of prospector is still found.

Most of the writers think that there is no need for additional money, as there is an ample supply of capital now seeking investment in mining, provided that thoroughly good properties can be found and investments in mines or prospects will be protected. If further funds should be required, they would be supplied by the public, if it were impossible for fake companies and wild-cat schemes to mulct the people. The restoration of confidence in legitimate mining ventures by means of the prompt prosecution of all swindlers and 'wild-catters' would be followed by a resumption of investment by the general public in mines and prospects or in exploration companies.

The giving of any monetary aid to prospectors by the government is unanimously condemned. It is thought that any financing or 'grubstaking' of prospectors by the government would lead to no good results, but on the contrary would produce a large class of loafers and professional parasites. The government can greatly assist the prospector, however, by increasing the activity and usefulness of the Geological Survey and the Bureau of Mines. For this purpose larger appropriations should be made for the prompt undertaking of work in new districts. The government

should attempt to do more pioneer work. A revision of the mining laws is generally demanded in order that the prospector and the buyer may not be subjected to uncertainty and annoyance with regard to his title and to constant litigation if he succeeds in finding a valuable orebody. The government should protect the prospector in his possession and development of his claims "by providing some method by which title can be safely and surely secured to undeveloped or partly developed mineral land, or land which is sufficiently promising in mineral possibilities to justify serious investigation," as Mr. Stanley Easton phrases it. Mr. J. W. Malcolmson says that "our imperfect and obsolete laws should be revised with special reference to the rights of prospectors." It is also urged by many that the government should aid the prospector by building roads, providing government assay-offices where ores could be tested at small expense, and by assisting in the provision of transportation and other facilities in new districts where orebodies of promise are being opened. Mr. Albert Burch thinks that the government should carefully prospect and classify its own mineral land. "Prospecting methods can only be improved in the United States by raising the standard of intelligence of the prospector," one engineer notes, and "this virtually means that prospecting will have to be done by trained men—mineralogists, geologists, and mining engineers—and on geological principles." "The large, prominent, rich croppings have all been found in every country that has even been partly explored, and now the search must be for concealed outcrops, hidden veins, and orebodies whose existence can only be suspected by analogy and the deductions from careful geological study," as is noted by a number. This kind of prospecting will require large sums of money, and will therefore be confined chiefly to the larger exploration and mining companies. At present the methods to be used are none too well understood and the laws are not well adapted to permitting the temporary occupation of a suitable area prior to discovery.

The demand for undeveloped mineral land will increase with the exhaustion of the present productive mines and increases in the price of metals. At the present time there would be a greater demand for undeveloped properties if the owners did not hold them at exorbitant prices, thus driving away capital which might make the properties productive. Some engineers estimate that fully 95 per cent of the owners hold their undeveloped properties at prohibitive prices. On this account a large amount of mineral land is held for years, by the performance of a little unsystematic work, without becoming productive, and the prospective investor is driven to other fields. Coöperation and a better understanding between the owners of prospects and investors willing to develop them would create a much better demand. It is rather generally felt that undeveloped mineral land is unattractive to investors because of the great feeling of distrust which has been engendered by the acquisition of such

lands by unscrupulous promoters for the exploitation of the public. The market for undeveloped lands could be greatly increased by the creation of "a stronger public sentiment against fake promotions and charlatan engineers and geologists. The postal laws can always be invoked to check this kind of fraud if people would take the trouble to go to the proper authorities with well assured facts. Fraudulent promotion has been a great deterrent to the legitimate development of the country. Of course, dishonest promoters would go out of existence if there were not so many foolish and avaricious people with money ready to put into their schemes. We cannot hope to eliminate the fools, but we could make it very hot for the promoters that use the mails," as Mr. F. Lynwood Garrison states it, and this sentiment is echoed by many.

According to most of those who discuss that phase of the subject, there is little or no danger of a metal famine for many years to come, although few mines are now being discovered to take the places of those that are being exhausted. In and around the large mining centres new orebodies are continually being opened in the extensions of the workings of the older mines as well as in new properties, and the improvements in mining, milling, and metallurgical practice are continually making available millions of tons of ore which was unprofitable heretofore. With increasing scarcity of any metal, it is thought that rising prices will so increase the potential reward that active search will bring out ample supplies.

Mining, no more than any other industry, can continue unless money goes into development. More ore must continually be found, and more ore will be found, but just where and how to spend most wisely in search of more ore, is a problem that remains unsettled, and which, we believe, is not capable of universal and sure solution. We approach the question with certain prejudices growing out of the history of the industry. It is a tradition that an orebody is a treasure trove, and, just as every man thinks that with sufficient paper and pencils, he could write a 'best seller,' so he thinks that if he really wanted to and had a pick and a comfortable camp outfit, he could find a mine. From time to time the inexpert do make discoveries, and thereby further establish the dictum that in finding mines expert knowledge is unnecessary. A few of the inexperts stay in the business long enough to become expert—and a real prospector is expert, indeed. The picturesque vagabond who depended on whisky and luck, and the new-style claim staker who depends on the printing-press and the mails, die hard. Fortunately, the well informed, really expert prospector is also far from extinct. We anticipate that our discussion department in the weeks to come will bear evidence of the fact. Equally fortunately, he has, as the letters printed show, the confidence of moneyed men quite as much as ever. There is plenty of money for sending him to any virgin territory where his methods offer a reasonable chance of success. The practical problem is to develop a new system for the

finding of lodes in the combed-over territory.

In the meantime, the mining companies are furnishing metal as fast as the market demands it, as is shown by any careful study of prices. Despite the 'increased cost of living,' which has affected mining as well as other industries, there has been no consistent or general increase in metal prices in the last quarter century; except in the case of tin, where there is an admitted shortage. The increased demand has so far been met by finding new veins in old districts, by development of extensions of known orebodies, and by lowering production costs and increasing extraction so as to convert into ore what was formerly waste rock. Presumably there will some day be an end to this. No extraction can be more than perfect, all orebodies do have limits, and there is a minimum cost below which a ton of material can not be handled, whether it be gold ore, coal, or clay.

The world is not coming to an end and people are not going to cease using metals. New deposits will be found and the open field is in the search for blind lodes. That requires skill, and money. The old prospectors as a class do not have that skill, and a new order of prospectors must be developed. It is insight, not numbers, that is needed. The geologist has some of that, but he falls far short of having all that is needed. Some time ago we suggested that the United States Geological Survey had a large responsibility and a magnificent opportunity in this connection. Our suggestion has been partly misunderstood. Mr. Albert Burch believes that the Government should prospect its own lands, and we believe that something along that line can be done to advantage, but it is much more important that the organization that has the largest fund of information and at the same time the entire confidence of mining men, should do its share in developing the new methods that we must have. Whether the Geological Survey found a mine or not, would be relatively unimportant if it pointed the way to the finding of mines. The suggestion that young technical graduates be put with old prospectors has much to commend it, as both the prospector and the graduate would learn much that would be useful; but that is a detail of administration. We heartily agree with the unanimous sentiment of our contributors that direct government aid to prospectors would but lead to waste and graft. The gradual extension of the excellent work already being done by the Geological Survey and the Bureau of Mines is more to the point and will meet the situation, but specific attention is needed to the general methods of prospecting. Occasionally Mr. J. F. Kemp lets his imagination play around to the subject of how to find minerals without sinking or drilling, and the result is a delightfully humorous essay that we all enjoy; but in sober earnest, why should we not hope for improvement along these lines, and why should not a reasonable sum be constantly expended, under proper direction, in the search? The prize is worth the effort, and the field of the unknown stretches to a far horizon.

What is the Matter With Prospecting?—IV

A SYMPOSIUM

Ralph Arnold:—I have found it true that money is no longer available in adequate amounts for finding or developing prospects. The only way that additional money can be made available is for people to organize small syndicates for carrying on preliminary developments, after which they can secure all the capital necessary if their mines show large bodies of blocked ore. It is quite easy to secure money for developing oil prospects; in fact, much easier to secure money for this than for investments in proved and developed properties. I do not believe in government aid to prospecting or prospectors, except that I believe our land laws can be modified so as to protect the prospector, which will naturally stimulate work along this line, especially prospecting for petroleum. A better market for mineral lands can be created by educating the prospectors to consider reasonable terms for their holdings when they have little absolute proof of the value of the property. Most prospectors want to sell their holdings for a cash value equal to the amount of money that probably can be taken out of the property, not on the basis of what is absolutely proved.

J. R. Finlay:—I do not believe it is true that money is no longer available for finding and developing prospects. The proof of this is, that metals are being produced at normal price, at least with such fluctuations in price as have always occurred. The decline of old-time superficial prospecting in this country is simply the inevitable decline which must come when the surface is pretty thoroughly known. No one would think of encouraging prospecting in England or in Massachusetts, because those countries are full of people. I believe that discoveries of mineral deposits in this country from now on must depend mainly upon more expensive and scientific prospecting, and will consist mainly of extensions of deposits already partly known.

A. D. Foote:—We must realize that most of the easily found deposits have been found, especially those that can be found by men ignorant of geology. To find more mines, therefore, it is necessary that men of knowledge and experience should hunt for them. When the demand is sufficient, such men will be sent out properly equipped and financed to find and work prospects up to mines. There is plenty of money available for this purpose. The greatest detriment to new mining now is the easy way by which a location may be held year after year by anyone. There are thousands of claims held by men for a nominal hundred dollars per year who want thousands for a mere hole in the ground. Gradually these holders are getting worn out and are willing to sell at a proper price, and it is here that we are going to find most of the

mines of the future. The old prospector has had his day, and the sooner he realizes it and lets up on his grip on the holes he keeps all over this country, the sooner new mines will be found. I disapprove most decidedly of government aid to prospectors.

R. C. Gemmell:—It is my belief that, at the present time, money is not available in adequate amounts for prospecting and for the development of mineral claims, but I think this is due very largely to the unsettled condition of business. With the improvement in business conditions in this country and abroad—which is bound to come sooner or later—capitalists will be anxious to get their surplus money profitably invested, and they will then take a much greater interest in mining projects. More money would be available for prospecting and for developing claims if more small syndicates or associations were formed for the purpose of handling claims, and I believe that such syndicates will be organized when business becomes better and money easier. It does not seem to me that the Government should be called upon to give financial aid to the prospectors. The Government could assist by being more liberal in its mining laws, and by giving greater protection to prospectors and locators of claims who have complied with all the laws and regulations in the location of their claims. It is possible that it might be practicable and advisable for the laws to be so modified that the government would protect the locator of claims, who has complied with all the requirements of law, against claim-jumpers and adverse litigation. I do not see how a better market for undeveloped mineral lands can be created at the present time. When times are better, perhaps some plan could be promulgated that would enlist the concerted action and support of the men who are actively engaged in the mining industry. The Eastern investor is a speculator in stocks and is not a buyer of mining claims. Any plan of this kind would, therefore, have to be developed and carried out by the mining men of the West.

Charles W. Goodale:—The impression does not seem to exist in the Butte district that money is no longer available for finding and developing prospects, but if that is true in other mining districts, I think it may be accounted for by the fact that there is a lull in mining activity generally, and that this has been brought about to a great extent by the fact that a great deal of money has been lost in Nevada and elsewhere in questionable mining schemes. As president of a development company having funds available for developing favorable prospects, I have been impressed by the fact that many owners of claims are unwilling to make agreements on a reasonable basis. They

nearly always insist upon a cash payment before work is commenced, and do not distinguish between a company having funds on hand for immediate development and the adventurer who is simply taking options upon mining claims in the hope that he may be able to interest capital in the scheme, giving him a commission for having brought the property to their notice. It is to be suspected that in some cases, at least, the owners are afraid that a little work will "spoil the best mine in the Rocky Mountains." The prospector is very apt to tell us that all his property needs is depth, but he is generally unwilling to let us determine by doing some work whether depth is the only thing needed, unless we are disposed to give him some cash for the privilege. Some of my friends here are inclined to attribute the depression in prospecting to the regulations of the Forest Service, for since the setting apart of large areas of Rocky Mountain lands for forestry reserves the prospector is subject to scrutiny by forestry agents in any work which he may do, and in many cases these agents are not competent to pass upon the question of whether the prospector has made a valid discovery or not. I do not see how government aid can be given to the prospector except in such a way as is carried out in British Columbia, where the Government is inclined to aid in the development of new country by spending money for wagon-roads and trails. I am inclined to agree with H. C. Cutler in his remarks, in your issue of November 22, 1913, when he calls attention to the fact that there is hardly any area of new country which has not already been run over by the prospector.

James W. Malcolmson:—I believe it is quite true that at present money is obtained with greater difficulty than formerly for finding and developing prospects in the United States. This is probably because the country has been already explored very carefully and the number of undiscovered mines left with ore outcropping at surface is small. The chance of easily finding a mine, or of discovering a mine at all, is very much less than in former years. Another reason, perhaps, is because in past years the speculator did not have a 'square deal,' much of the money subscribed for mining ventures having been expended improperly before reaching the mine or prospect. There is usually an increase in the amount of money invested in mine exploration following a general rise in the prices of securities on the New York Exchange and elsewhere. This is because many holders of stock are able to sell with profit and without personal effort; such persons are always inclined to gamble, in the hope of discovering or developing a new mine. Government aid should be given to prospecting and prospectors by relieving them from the most and costly burdens now imposed on them. Today if a prospector discovers a mine in the United States he is immediately assailed by a number of adverse claimants, a condition which is the scandal of every new mining district. Instead of receiving protection, the discoverer finds the law

used to destroy his rights and to impoverish him. Prospecting methods can only be improved in the United States by raising the standard of intelligence of the prospector. Unfortunately, however, if this be done under existing laws and legal methods, the individual will thereupon probably cease to be a prospector. The market for undeveloped mineral lands will be improved by the advance of lines of communication, such as roads or railways, by an increase in the value of the metal in the ore, a decrease in the costs of operations, or in general by anything which will enable the miner to operate undeveloped properties more profitably than before.

W. W. Mein:—Money is available to support prospecting, and prospectors are available for the work, just as long and as plentifully as results prove favorable. The only factor required to stimulate enterprise is success, and the present phase of comparative inactivity is due to lack of recent finds of great importance. The area of unknown territory is constantly decreasing. Further, when prospecting is most active, it is generally the most wasteful and poorly directed. The natural laws governing the situation lend themselves little to control by artificial measures. The practical utility of government aid to prospectors is largely a matter of historical and physiographical conditions. In a little developed, heavily timbered, and mountainous country like British Columbia, the prime function of the Government toward prospecting should be in the improvement of roads and trails, as is creditably recognized by the provincial authorities; in California, the most valuable work of the state lies in the collection and distribution of accurate knowledge, so that past experience can best be applied in the search for new occurrences; in a desert country like Arizona, where the outcrops are usually less obscured, the most direct aid to prospectors might lie in the loan of state drills, as in Western Australia and Nova Scotia. Broadly, I feel conservative in my views of governmental relations to the speculative industry of mineral exploration. Fearing the danger of faddist legislation more than the effects of undue indifference, I prefer to see official energies confined, almost exclusively, to the geological surveying, statistical and publicity work, and the fundamental duty of improving the accessibility of difficult regions.

Reno H. Sales: It is my opinion that it is not true that money is no longer available in adequate amounts for finding and developing prospects. We all must realize that the most easily found good things have already been taken up, and therefore prospecting for hidden outcrops, blind veins, etc., has come to be a matter of much more expense than in early days. I am inclined to think that additional money can be made available only by reason of conditions under which there will be greater demands for the various metals. I believe in government aid to prospecting and prospectors to a certain extent. Canada is far in advance of us in one respect, and that is in the matter

of building wagon-roads to inaccessible properties. As far as my experience goes, the prospector in this country receives no help along these lines, until he has developed his prospect into a producing mine, and then help comes only from the county in which the mine is situated. Even then the help is so much delayed that it is of doubtful value. The conservation movement has had its bad effect on prospecting in this country, and this is especially true when it is realized that it is becoming more expensive now to find veins than it was in former years. The establishing of government assay offices, where assays could be made for the prospector at a slight expense, would be of some benefit. A good service could be rendered to the prospector, and the mining industry, by increasing the field forces of the U. S. Geological Survey.

F. F. Sharpless:—There is not so much money available today as there once was for grubstaking and the development of prospects. The reasons for this are numerous, but among them one stands out prominently, and to my mind is all important. I refer to the fact that a different condition of affairs confronts the prospector of today from that which confronted his father and grandfather. In other words, the chances of the prospector of average intelligence have grown less from year to year as the more easily prospected ground has been taken up and eliminated from his available hunting ground. We hear of few new and important finds, not so much from the lack of prospectors as from lack of important discoveries made. The backer of the prospector—that is, the local merchant, saloon-keeper, hotel proprietor, etc.—failing to reap returns as he formerly did, is growing less and less inclined to furnish the grubstake which is as necessary as the prospector himself. I doubt much if it would be possible to get up a real good old-fashioned mining boom on short notice, even with the proper settings; it would certainly require some very high-grade ore and high-grade advertising; but, if the prospector is to have his innings again, this is the most likely way in which he can secure his ample funds. People who make a business of mining have learned to stick to mining rather than to attack the prospecting business. It pays better to buy at a price something that has been developed than to pay nothing for a prospect and develop it into little or nothing. Prospecting by the larger companies has been conducted on lines too closely resembling those adopted in the handling of a mining property. The care and refinement with which the prospects have been handled have cost too much, the money set aside for that work has not gone far enough, the company has not been able to investigate as many prospects as it should, so the result has been rather discouraging. Some day this side of the mining business will be so developed, so thoroughly understood and capably handled, that money for legitimate business will not be lacking. Government aid to prospectors is practicable along these lines, mainly through the revision of mining

laws. The Government may not be able to throw open to the prospector land that has already been deeded to another, but in the future it can draw these deeds to surface rights in such a manner that later, if the prospector cares to, he will have an opportunity to investigate what is under the surface.

W. Y. Westervelt:—To my mind there is little doubt that the number of old-time prospectors is steadily lessening. Further, it seems to me inevitable that these men will eventually disappear entirely, at least from the territory occupied by the present states, as the natural result of the disappearance of wilderness sections. The prospector is essentially a frontiersman and pioneer. His methods are adapted primarily to wild life. His search is for rich deposits but little concealed beneath the surface, and his reward must be secured, if secured at all, through a rich find which will yield large and quick returns with comparatively little capital investment. As is well known, the development of new camps in recent years has been largely due to the proving of large low-grade masses of ore by heavy expenditure in districts long known to be mineral bearing and long since passed from public to private ownership. The prospector did his part in them many years ago by noting and reporting the presence of valuable mineral. As soon as he became convinced of the unlikelihood of the presence of bonanzas, however, he either moved on to more promising fields or settled down on his claims while awaiting the opening up of his district by large capital with its all-essential transportation facilities. The prospector of the future, and I am inclined to think of today, is the development company which combines practical geological, engineering, and business skill with capital. Such companies can take the risks of extensive prospecting by sinking and boring, of technical investigations, of experimental plants, etc., necessary to establish the existence, quantity, quality, and feasibility of working large low-grade or refractory deposits.

Louis A. Wright:—I am of the opinion that there is plenty of money available for development of attractive prospects, but that the active search by financially strong companies or individuals has waned considerably during the past year. Additional money would be available immediately in any given district if a success were made of a group of claims and sufficient area not included in such a group were available for development; that is, there would be many people looking for chances in the district, provided that the promising ground was not all held by the successful corporation or individual. I most emphatically do not believe in government aid in prospecting. I personally know a good many cases in which undeveloped mineral lands would be worked if owners' prices and terms were more reasonable. It seems to me impossible to remedy this condition until prospector-owners have been further educated and brought to a better understanding of business on a reasonable basis. They

Supplement to THE MINING AND SCIENTIFIC PRESS, Jan. 31, 1914.

ARTIST'S SKETCH OF THE PLACER MINING QUADRANT
of the Proposed California Mining Exhibit
Panama-Pacific International Exposition, San Francisco 1915

California Miners and the Exposition

By CHARLES E. VAN BARNEVELD

In just one year the exposition to be held in San Francisco will open its doors to the world. Many look upon an exposition as a gigantic and expensive commercial advertising scheme. Nothing could be farther from the mark. While it has legitimate advertising possibilities from the standpoint of the exhibitor, the motif is educational; to bring together men and women from all walks of life and from all activities so that each may learn what the other is doing and how it is done. If a number of public-spirited men were to get together and ask themselves, "What can we do to promote the welfare of industrial and professional America, to show our triumphs and our shortcomings, to set a mark for progress, to promote a better understanding among the nations, among the various states, among the industries?" the answer might well be: promote an international exposition. An exposition always inspires new ideas, gives impetus to inventive genius and to powers of execution, and makes for decided progress.

What the Exposition Means

This exposition will be a record of the history of the world's progress in all the arts and industries; an inventory of the world's status at the commencement of this new trade era presaged by the Panama canal. Its exhibits, gathered from all over the world, will tell the casual observer, the student, and the thinker, by object-lessons instead of by words, what mankind is, does, and seeks to do. It will be a living picture illustrating and interpreting the cold and bare statistics which, without such interpretation, are incomprehensible and meaningless to the average mind. It is, therefore, the privilege and the duty of each industry to properly represent its activities, each industry being in turn host to all others.

What is California's mining industry going to do, on the one hand, toward making a success of the exposition, and, on the other hand, toward making the most of this opportunity to display intelligently and attractively its mineral resources to an audience drawn from the four quarters of the globe, and thereby uphold the prestige of the industry which has played so important a part in the development of the state?

The history of the opening, development, and settlement of the western United States is the history of the prospector and miner. This is especially true of California. The lure of gold, following Marshall's discovery in 1848, drew to the Pacific Coast the mighty throng of intrepid pioneers whose splendid achievement wrought the present western civilization, the climax of which is seen in the construction of the Panama canal, that great trade shortcut, which has been appropriately referred to as "the greatest

liberty ever taken with nature."

The great gold belt of California which stretches for a distance of 250 miles from Mariposa to Plumas county, is one of the most impressive mining spectacles on earth. Since 1849 this territory has created new wealth at the rate of \$2,000,000 a month. After adding over one and a half billion dollars to the purchasing power of the nation, California is still in the lead in American production. The oil industry of California is of paramount importance to the future development of the state. The great westside oil fields, from Coalinga on the north, stretch southward in one unbroken formation to the Midway-Sunset field, a distance of nearly 150 miles. The coast fields occur in a stretch of territory covering four counties, within which are geologically connected areas of great productivity. Petroleum and its products occupy a large place in the commerce of the world; in fact, no industry surpasses the petroleum industry in magnitude and diversity of operations. Capital the world over is eagerly seeking new fields. Governments realize the advantage from both a naval and a commercial standpoint of having a dependable and readily accessible supply. California's store of petroleum is one of its richest endowments. As the premier oil producer, the world looks to this state to make such an exhibit of the industry as will mark a new epoch in its history.

Why Mining Should Exhibit

There are some who feel that in addition to altruistic and patriotic reasons for devoting time, thought, and money to an exhibit, they must have a good business reason. On the cover of the official call of the American Mining Congress, there appears this statement regarding mining: "It is the one indispensable industry; through coöperation only can its importance command recognition and the best results be accomplished." This was followed by the invitation, "Come, let us reason together." That is exactly what the exposition offers you: an opportunity to reason effectively with the public, with a select and highly influential portion of the public—the thinking public—in a way that will make a lasting impression. The mining industry of the country at large is not flourishing; it is not receiving its due share of attention. Among the basic reasons for this is public misinformation and mistrust. One of the greatest assets an industry can have is public confidence, for that means public sympathy and coöperation. We all recognize, in a general way, the importance of education; it is the greatest remedy for prejudice, superstition, and ignorance; it makes for greater all round efficiency. A well planned exposition is of incalculable value

as an educator of the public mind, and no industry is in greater need of this service today than mining. Many important questions in which the miner is vitally interested are pressing for settlement. The public is taking an increasingly active part in forcing these settlements. When not blinded by prejudice and ignorance, the public is essentially fair-minded; it only needs to be educated. You have before you now an opportunity which probably will not recur for a decade to give the public an insight into the importance, stability, and solidarity of your industry, its legitimate speculative and investment features, your need of capital, of fair treatment, of wise legislation, of public support and coöperation. Surely this is sufficient commercial incentive.

In considering this question from the standpoint of an industry which has no direct interest in stimulating the retail markets of the country, we are prone to allow the lack of apparent direct individual benefit to blind us to the decided indirect, collective benefits to be derived from the right sort of publicity. Every mining man should see in this exposition an opportunity for some broadcast sowing. The higher he has risen in his profession, the more important the enterprise he owns, directs, or is associated with, the greater will be his opportunity. To approve the sentiment that the industry should be properly represented is only the first step. While the result will be collective, the responsibility is individual, and only as the individual interests himself in the matter will we attain results.

The mining industry of California has been struggling under disadvantages, many of which could be removed by an educational campaign. The exposition offers an opportunity to those interested in copper smelting and gold dredging to show what these branches of the industry mean to the state. The smeltermen could show what they have done toward suppressing the smelter fumes, which at one time threatened to extinguish this important industry. The dredgers could show the progress they have made in re-soiling dredged areas and restoring them to the horticulturist in an improved condition after adding millions annually to the gold production, thereby stimulating every industry in the state.

The Public and the Oil Industry

The American public, on account of ignorance, has failed to interest itself sufficiently in the oil industry of California and has failed to supply the necessary capital for a proper development of this state's magnificent oil resources. It appears, however, that foreign capital fully recognizes the opportunity for investment in California fields, and there is increasing danger of our industry falling into alien hands. California should conserve this magnificent heritage to its own use: it should not have to pay tribute to foreign capital. The exposition offers the oil industry an opportunity to make a collective educational ex-

hibit which will make a lasting impression on the public mind.

Many of the states can point to a much larger mineral production than can California, but none can point to a combination of like potential value. California is the leader among this nation's gold producers, creating yearly \$20,000,000 of new capital. California is the leader in petroleum production, with roughly 40% of the American production, or about 25% of the world's production; the heaviest producer among the states by over 60%, exceeding the output of the heaviest foreign producer, Russia, by over 40% (1912). Not only does California, through its vast oil resources, command an abundance of cheap fuel which is an aid to transportation, mining, agriculture, and horticulture, and a stimulus to manufacturing industries, but the lighter California oils have a great potentiality as raw material for many lines of manufacture as yet undeveloped.

Minor Metal Production

Besides leading the world's oil production and heading the American gold production, California is credited with the entire American borax, magnesite, and chrome production. To this must be added such important products as: copper, running up into the millions and destined, on account of its wide distribution, to assume far greater importance; quicksilver, to the extent of furnishing 80% of the American production; cement to a value of \$8,000,000; and many other products making a grand total of \$91,477,385 for the year just ended. It is a notable fact that each of California's 58 counties contains mineral deposits of some description and with very few exceptions all of them produce commercially.

It would seem as though an industry of such magnificent proportions and of such wide importance should do something more than have a series of unrelated county displays. It is entirely proper for the counties to wish to make a display of their various resources, agricultural, horticultural, forestry, mineral, and oil, in the California Counties building. Each county can thus draw attention to what it has to offer the investor and the homeseeker in each line. Such an exhibit has its rightful place: it is, however, merely an exhibit of mineral resources and very far from being an industrial mining exhibit, which latter is a graphic portrayal of the mining industry, without which the mineral exhibit would be flat and unprofitable. The exhibit which impresses the public and teaches the valuable lesson is the complete exhibit which begins with undeveloped mineral resources, ends with the article sold to the retail trade of the country, and shows, in so far as possible, intermediate processes. The public must be educated regarding the importance of the mining industry. The right kind of an industrial exhibit will teach them the lesson in coöperation which they need. They do not realize the problems of the industry, its need for public support and coö-

eration. A beautiful collection of mineral and ore specimens, or a well lighted and well arranged collection of crude and refined oils, attracts the color sense, the sense of the artistic, and very little else, unless it forms a link in the complete exhibit of the industry. The mining man who knows all about mineralogy, about ores and their occurrence, is interested in these mineralogical exhibits because he has the supplementary information needed to make the exhibit instructive. The thousands who know little or perhaps nothing about the details of mining see in it something pretty and attractive, but it does not teach them a lesson. An exhibit which does not teach a definite lesson is a waste of money and effort on the one hand, a waste of valuable space on the other.

Need of a Central Exhibit

The proper place for California's mining and oil exhibit is unquestionably the Palace of Mines and Metallurgy—in a mining atmosphere, in competition with the mining exhibits of the other states and nations. There is where the world will expect to find it, and unless it is made there, the world will not see it. Everyday life teems with illustrations of the value of coöperation and united effort in a common cause. The mining industry of the state is far greater than that of even the leading producer among the counties. Then, aside from questions of the right kind of public spirit, industrial and state pride, would it not be a good business policy to draw the world's attention to the greater? A county would unquestionably derive more individual benefit from a comprehensive, well worked out, complete state exhibit of an industry than it would derive from the same amount expended on an individual exhibit. This is merely another striking case where coöperation will bring results which cannot be secured in any other way. Furthermore, the counties need not lose their identity under this plan. There are other, more dignified, more effective ways of attracting attention to a county's position than by needless duplication of exhibits. The counties could at best make relatively small individual exhibits of minerals, ores, and oils supplemented by photographs, maps, and an occasional model. There would be an endless array of these individual exhibits and much inevitable duplication. Such exhibits are tiresome to the visitor who has heard much of California's wonderful mining history; they are disappointing to the visitors from other states, and from all over the world, who have come to see and learn something about the mining industry. Collectively, the industry can make an exhibit which will be spectacular, beautiful, instructive, and which will impress the world with the importance of the mining industry of the state and therefore with the importance of the mining and oil-producing counties. That is what the state wants, and what the counties want. Unfortunately, no funds have been provided for a state exhibit. To remedy this deficiency, I suggest that the counties unite in

financing such an exhibit out of the exposition funds which they are raising by taxation.

In the centre of the Palace of Mines and Metallurgy, under the dome, which towers to a height of 160 ft., is a space of 150 by 200 ft. The main aisles from the four entrances to the Palace converge toward this space, so that it naturally divides itself into four quadrants, each one opposite a main entrance. This is the choicest space in the building, and I would like to see placed in it a mountain having a peak of 45 to 50 ft. Each quadrant of this mountain, facing a main entrance to the building, would be finished to represent some main subdivision of the industry. One of these could represent an important oilfield reproduced in such detail as to give a comprehensive idea of California's wonderful oil industry. Another, a placer mining section to include primitive methods, a reproduction of the La Grange mine with giants throwing streams of 20 to 25 ft. in length, and at the base of the mountain a working model of a dredge showing all operations in detail. Another section could show the copper industry. The fourth side could be devoted to the representation of quartz mining. Several veins might be shown, one being prospected with the meagre equipment characteristic of prospecting work, another fully developed, producing, and fully equipped. A section of the mountain could be cut away here, and behind a plate-glass front the underground working details could be shown.

Such an exhibit would, on account of its prominent position, visible from each of the main entrances, on account of its completeness, its unique features, its very boldness, surpass anything in the building and would make California's exhibit the centre of attraction. The expense, viewed in the light of its being the exhibit of an industry which in one year produces over \$90,000,000, would be relatively small. It would have a tremendous stimulating and otherwise beneficial effect on the industry. The state's debt of acknowledgment to the pioneer miner would be complete. The miner's pride, his community pride and his industrial pride would be satisfied.

Coöperation Essential

This plan insures the best state and the best possible counties display at the least cost and under conditions where each one's exhibit reinforces and is reinforced by his neighbor's exhibit. Each county might rightfully say, "this is our mountain." The quartz counties could exhibit opposite the quartz section of the mountain; the placer mining counties opposite the placer section; Shasta county opposite the copper section; the oil-producing counties' individual exhibits would be deployed in magnificent array around the oilfields. If this plan is carried out, the mineral industry of California will present a solid front, will be the centre of attraction, and, best of all, the various natural subdivisions of the industry and the individual counties will maintain their individuality.

Electric Blasting in Shafts With Delay Action Exploders

By C. W. MORSE

Blasting with electricity in shaft-sinking is not receiving the attention it deserves. The principal reason seems to be that comparatively few mine superintendents and engineers are familiar with the delay-action exploders as perfected by the California Cap Co. The largest powder company in the United States attempted to perfect such an exploder, but was not entirely successful. Charles S. Hurter, whose article, 'Electric Blasting,' appears in your issue of November 8, was a member of the technical division of that Company at the time. Had he been familiar with the California product, I believe he would have recommended it strongly, not only in shaft-sinking, but in driving and raising in close places.

Shaft-sinking is an anxious period with most of us, and anything that will render it less dangerous is surely welcome. The delay-action exploder is something that many of us have hoped for. These exploders were used in sinking the South Jackson shaft, at Jackson, Amador county, California. The superintendent, Jeffrey Schweitzer, reports that they were most satisfactory. Jack Collier tried them later at the Sultana mine, at Grass Valley, with equally good results. The exploders are made up with an electric fuse igniter, a short length of time fuse, and a detonator, all contained in a waterproof covering. They are made in ten periods; the different periods being obtained by varying the lengths of fuse. The longest will go into the regulation stick of powder. They can be obtained with any length of wires.

In blasting in a wet shaft, current should be taken from the light circuit, as there are many sources of leakage and the ordinary blasting machine will not supply sufficient current. Two wires are brought from the light circuit to a small box which should contain fuses of lower amperage than those on the light circuit, a knife switch opening down and held open with a weight or spring, and two binding posts; an indicator lamp is convenient. This box should have a lock for which the blaster only has a key, and should be placed near the collar of the shaft or at a convenient station. Nearby is a reel for holding and playing out a No. 10 encased cable. The inside end of the cable is left protruding sufficiently to permit its being connected to the binding posts when the box is opened.

The cable reaches to within a few inches of the bottom of the shaft, and to each of its two wires a length of bare telephone wire is attached and placed horizontally across the shaft, being kept off the bottom with blocks of wood. To these wires the exploders are attached in parallel by the insulated wires with which each is supplied. In loading the holes the first delays are, of course, used in the cut holes. For most work, five periods of delay are all that are required.

When the men, including the blaster, reach the sur-

face, the blaster unlocks the box, connects the ends of the cable to the binding posts, and throws the switch. At the South Jackson, they took the additional precaution to have a break in the cable, the ends being held together during the blasting.

All miners can recall many horrible accidents that would have been avoided by the use of this method of blasting, and not only are accidents avoided, but the fumes from long lengths of burning fuse are also done away with, and the air in the shaft is rendered less foul by the round.

A Motorcycle Hoist

The figure with this shows a successful application of a motorcycle to hoisting ore at one of the leases on the Stratton Estate property at Cripple Creek, Colorado. The lease operator, Jerry Mackey, after riding his machine to the mine in the morning—a long uphill pull, by the way—then puts it to work at raising the ore on his lease. For this purpose, the motor-

MAKING THE MOTORCYCLE WORK.

cycle is held tightly in a wood frame, and a long chain run from the sprocket, past the front forks, to a gear-wheel on the hoist.

The hoist is of the geared type ordinarily employed on hand derricks for quarry work. The duty demanded of this outfit is hoisting a total load of about 300 lb. from a depth of 90 ft. One man can handle the engine, and dump buckets at the shaft top; and the hoisting is much more rapid than would be the case with the usual whim. Mr. Mackey has placed a powerful band brake on the drum, and for additional safety there is a ratchet dog in mesh during hoisting, which is held up during the lowering of the empty bucket. A flexible steel cable is used in preference to hemp rope.

Diamond-Drilling at Ajo, Pima County, Arizona

The recent announcement in the *Mining and Scientific Press* that the Calumet & Arizona Mining Co. had exercised its option to purchase the New Cornelia property at Ajo, Pima county, Arizona, recalls the interesting fact that this is the first of the large low-grade copper deposits to be thoroughly explored by diamond-drills. It is needless to say that the Calumet & Arizona Mining Co. had given the Ajo property a thorough examination before securing an option late in the summer of 1911. It determined to do a small amount of work at first, and laid out a plan which called for drill-holes approximately 200 ft. apart.

Although having an organization and equipment of its own, the Company asked for bids from independent contractors, on a small amount of diamond-drilling as a preliminary test. The contract was awarded to the E. J. Longyear Co., exploring engineers, of Minneapolis, Minnesota. The work, beginning in November 1911, resulted satisfactorily, and a much larger amount of drilling was decided upon. The exploration continued until June 1913, when five outfits were in operation and approximately 25,000 ft. had been drilled. The geological and engineering departments of the Calumet & Arizona company had charge of the work, and with the representatives of the E. J. Longyear company spent a large amount of time and money in determining the best method of sample recovery. The method finally adopted for collecting the sludge consisted in the use of a number of steel barrels or small tanks, which were filled in rotation from the drill, no overflow being allowed. As the sludge in the barrels settled sufficiently, the clear water was drawn off by a siphon. The residue in the barrels was then carefully collected into one barrel and again set aside to settle, after which, the clear water having been siphoned off, it was poured into tubs and taken entire to the drying racks, dried, and quartered down to the desired volume.

The core recovery was excellent, considering the nature of the rock, and composed an important part of the sample. It also afforded an opportunity not otherwise obtained for geological study of the character and occurrence of the ore. Both single and

double-tube core-barrels of the standard 1½-in. size, outside diameter, were used, and a minimum of 'grinding core' resulted. The shattered and fissured condition of the rock offered abundant opportunity for the loss of water, but the methods used for casing and cementing prevented delay on this account, as an extra outfit was always at hand, to which the crew was transferred. The crew did not continue drilling after the bit blocked, nor when the flow of water was insufficient to procure a proper sample. The diamond-drilling was checked in several instances by test shafts sunk on the drill-holes, and the results show the reliability of the drill samples.

The machinery used consisted of the E. J. Longyear Co.'s 'UG' drills and one hydraulic. The 'UG' is a light, two-cylinder, screw-feed drill of steel construction, and proved very satisfactory and convenient, and especially adapted for this work, a large proportion of the drill-holes being on the sides and tops of steep, bare, rock hills; moving from hole to hole having to be done almost entirely by hand. The work as a whole did not offer any difficulties that could not easily be overcome, although the operating conditions were somewhat complicated by the situation of the camp, necessitating a 50-mile haul from the railroad. Among other features dealt with were a very limited water-supply for drilling purposes, and excessive heat at times requiring a modification of the usual working hours. The closest and heartiest coöperation was maintained between the mining and exploring companies.

That diamond-drilling is the logical method of exploration in the Southwest, as elsewhere, is argued from the fact that the equipment is a collection of comparatively small units easy of transportation, that holes may be drilled in any desired direction and an excellent opportunity afforded for studying ore formations by inspection of the drill-core. The fact that so progressive a company as the Calumet & Arizona has used this method and found it satisfactory, and has adopted it in exploring its low-grade copper properties, suggests that the diamond drill, under careful direction, may occupy a much larger place than it has heretofore held in the development of the West.

The Speel River Electro-Chemical Project

By W. P. LASS

The Alaska Hydro-Electro Chemical Co. contemplates the development and utilization of hydro-electric power in the vicinity of Speel river, southeastern Alaska. From the data available it is estimated that from 40,000 to 100,000 hp. that may be developed from the river and the lakes adjoining by a capital expenditure of less than \$40 per horse-power. Detailed estimates by E. P. Kennedy have already been published.* The cost of electric power at Speel river, allowing 8% interest on the investment, will not exceed \$5 per horse-power year, it is believed. Were a lower rate of interest obtainable the power costs would be decreased accordingly. This is much below any known power development in the United States and compares favorably with that of Norway.

The selling price of power at Niagara Falls varies from \$8 per horse-power year for those buying only the water rights and putting in their own machinery, to \$20 to \$25 per horse-power year for those buying the working current adapted for their particular use. In 1911 Niagara was producing 275,000 hp. of electric power. Of this total amount, 146,000 hp. was employed in the manufacturing industries attracted to Niagara Falls by reason of the cheap power. Of this 146,000 hp. so employed, 128,000 hp., or 87%, was used for electro-chemical processes. The Keokuk & Hamilton Water Power Co. has about completed the development of 200,000 hp. at the Des Moines rapids of the Mississippi river. The cheapest contemplated power in the United States is at the Dalles, on the Columbia river, where the cost is estimated at \$77 per horse-power for a 300,000 hp. development, and the cost of producing low-tension power at the station \$6.90 per horse-power year.

COST OF WATER POWER DEVELOPMENT IN NORWAY AND SWEDEN

| | Hp. | Head, ft. | Cost per electric hp. |
|--------------------------|--------|-----------|-----------------------|
| Joesefors, Sweden | 1,800 | 26 | \$70 |
| Frykfors, Sweden | 4,000 | 27 | 64 |
| Yngersfors, Sweden | 8,250 | 60 | 38 |
| Vamafos, Norway | 75,000 | 86 | 26 |
| Tya, Norway | 73,000 | 3290 | 36 |

Most of the above power is used for electro-chemical purposes. One plant at Notodden is now using 60,000 electrical horse-power in the manufacture of nitric acid from the air.

Much has been said of the resources of Alaska: the rich placer deposits of the interior, the vast coal and copper deposits to the westward, the large low-grade gold deposits in the vicinity of Juneau, and the extensive timber lands in southeastern Alaska; but little has been said of the water-powers of southeastern

Alaska that are allowed to run to waste, while millions of dollars are being expended for hydro-electric developments in other countries for the manufacture of electro-chemical products.

The proposed undertaking should not fail to meet the approval of all conservationists because it is "the application of common sense to common problems for the common good." In order to successfully undertake any large electro-chemical industry it is of prime importance to have: (1) a large amount of cheap power the year around; (2) accessibility to the market, location suitable for cheap transportation of products; (3) to have accessible the various raw materials to be used; (4) in order that the concern may operate most efficiently it is necessary that the industry be large and so varied as to allow the utilization of its various by-products and thus avoid waste.

Proposed Power Development

The proposed power is the hydro-electric power generated from Long, Crater, and Tease lakes, and Speel river. The industrial plant will be situated alongside the generating plant on Speel river. This allows for a deep water harbor for handling raw materials as well as the various marketable products. From the most reliable data at present available it is thought possible to generate electric power near Speel river in units of 10,000, 20,000, or 30,000 hp. at a cost not to exceed \$5 per horse-power year. Speel river is between Ketchikan and Skagway, 35 miles southeast of Juneau. It is but 10 miles from the course of all boats sailing from Seattle to southeastern Alaska and the westward by what is known as the Inland Passage. The present freight rate to Seattle is \$2 to \$4 per ton.

It is doubtful if the electro-chemical plants of Norway or Niagara would ever be strong competitors in the Pacific Coast markets, to a plant on deep water in a sheltered harbor in southeastern Alaska, 1000 miles north of Puget Sound, a location which would permit shipments to be made from the plant by barges to Puget Sound and San Francisco, or by boat direct to any foreign port.

As regards the supply of raw materials it would be hard to find a spot more favored. The surrounding islands are densely covered with timber and contain limestone, sulphur, and many other raw materials used in the manufacture of electro-chemical products. Suitable coal could be obtained by boat from the westward or from Vancouver. Oil may be obtained at a price of \$1 per barrel. An electro-chemical industry here would stimulate prospecting among the islands along the whole coast of southeastern Alaska and would supply a market for the gold- silver, copper, lead, and zinc ores and concentrates.

*See *Western Engineering*, January 1914, and *Mining and Scientific Press*, January 24.

The Speel river project consists of several individual lakes and a river so situated as to allow the development of 10,000 or 20,000 hp. for the same low capital expenditure per horse-power as would be required for the full development. The maximum amount of power which can be generated will depend upon the run-off and precipitation, records of which are to be gathered during the next few years. The run-off and precipitation records for the year 1913 indicate the possibility of developing 100,000 hp. Were such a power development possible it would mean the establishment of a large electro-chemical and industrial plant and would furnish permanent employment to several thousand men. The scope of such an electro-chemical industry would be the manufacture of carbides from lime and coke; of sulphuric acid from pyrites; of pig iron from clinkered iron; of pulp from wood and sulphur; of nitrates from the air; of explosives from nitrates and glycerine; of zinc and lead salts; of cyanide for treatment of gold ores; of cyanamide and fertilizers; of potash, silica, and aluminum from feldspar; of potassium and fertilizers from kelp; and the treatment of zinc and lead ores by electric furnaces.

Raw Materials Available

That there is a field for a large electro-chemical industry is shown from a consideration of the raw materials to be had and the demand for these when put into a marketable shape.

One of the limestone claims located on Speel river contains 15,000 tons of calcite above tidewater. Chemical analysis of this calcite is:

| | Per cent. |
|-------------------------|-----------|
| Calcium carbonate | 98.50 |
| Iron and aluminum | 0.31 |
| Insoluble | 0.22 |
| Water | 0.80 |

There is an abundance of limestone containing less than 1% magnesium and iron to be had on Admiralty island. For the manufacture of calcium carbide, lime should be pure and contain not more than 1% magnesium. The cost of producing one ton of calcium carbide from the raw material may be estimated as below:

| | |
|--------------------------------------|---------|
| 2000 lb. lime | \$ 3.00 |
| 1200 lb. coke | 6.00 |
| 4600 kw-hr. at \$5 per kw-year | 2.75 |
| Electrodes | 1.25 |
| Labor and repair | 10.00 |
| Interest and depreciation | 2.00 |
| Freight to Pacific Coast ports | 4.00 |
| General expense | 1.00 |

Total cost per ton of calcium carbide f.o.b. San

Francisco or Seattle

Assuming a market value of \$40 per ton, there would be a profit of \$10 per ton of calcium carbide marketed. In practice a power consumption of one horse-power year would be required to produce 1.5 tons of carbide, yielding a profit of \$15 per horse-power year of electric power generated. A carbide works having a daily capacity of 55 tons would cost \$150,000, and would re-

quire 13,000 hp. for which it would pay \$5 per horse-power year. After paying \$65,000 for power such an industrial plant should market 19,500 tons of carbide for \$30 per ton, at which rate it would earn a yearly profit of \$195,000. Such an industrial plan would be able to meet all operating expenses, fixed charges, interest and depreciation, and in three years' time earn sufficient funds to pay for its own works as well as the original power development costs. Or, paying 8% for interest and depreciation on the power development, it would pay dividends of 100% on the industrial plant.

In 1910 seven Norwegian carbide works used 60,000 hp. and marketed 50,579 tons of carbide. In 1912, Norway produced 64,000 tons valued at \$2,500,000. In 1909, the world's production of calcium carbide was 280,000 tons.

The chief industry of any electro-chemical plant would no doubt be the manufacture of nitrogen from the atmosphere, and the various products composed of nitrogen such as calcium nitrate, calcium cyanamide, cyanide, ammonium nitrate, and nitric acid. In 1910, Chile exported 2,308,000 tons of nitrates, and Norway produced 22,000 tons of nitrates from the air. One kilowatt year will produce half a ton of nitric acid by either the Pauling or Birkeland & Eyde electric furnaces. This acid would have a market value of 3c. per pound.

The use of 10,000 kw. would require 24 Pauling furnaces and five absorption towers, making an estimated cost for the industrial plant of \$500,000. Such a plant should produce 6500 tons of nitric acid having a market value of \$400,000. The cost of producing such an amount of acid would be:

| | |
|--|-----------|
| Operating and general expense | \$100,000 |
| 13,000 hp. at \$5 per hp-year | 65,000 |
| Interest and depreciation at 12% | 60,000 |

Total cost of 6500 lb. nitric acid.....\$225,000
Market value of 6500 lb. nitric acid..... 400,000

Profit 35%, or

\$175,000

Powder Making

Among the supplies of greatest interest to the gold mines of the West are cyanide and powder. At the present time cyanide can be imported from London, and after paying a duty of 25% be sold in Seattle or Juneau for the same price as our home product which has to be obtained from New York. The demand for cyanide will increase as the price is lowered; for instance, if the Treadwell companies were to cyanide their tailings the expenditure for cyanide at the present rate of consumption would be \$164,000 yearly. This cyanide could be manufactured at Speel river for one-third of the above cost. With the price of cyanide reduced, treatment of low-grade ores becomes more profitable. Cyanide could be manufactured at Speel river and compete in the open market at a price much lower than the present quotations.

The mines of Douglas island purchase annually

2,000,000 lb. of blasting powder. Should the Alaska Juneau and the Alaska Gastineau companies each use a like amount this would mean 6,000,000 lb. of powder manufactured in the United States from nitrates imported from Chile, although the whole industry could be carried on within 40 miles of the mines and the powder manufactured at a smaller cost.

Acid Making

The Treadwell companies produce yearly 30,000 tons of pyrite, having the following chemical analysis—and no market value: iron, 34%; sulphur, 32%; gold, \$1.25 per ton; arsenic, none. This pyrite could be concentrated into 20,000 tons having the following chemical composition: iron, 45%; sulphur, 40%; gold, \$1.50 per ton. It could be delivered to Speel river for \$1 per ton. The cost to Treadwell companies for marketing pyrites would be:

| | |
|---|----------|
| Washing 30,000 tons, at \$0.10..... | \$ 3,000 |
| Loading 20,000 tons at \$0.15..... | 3,000 |
| Freight to Speel river on 20,000 tons, at \$0.70..... | 14,000 |

Total\$20,000

These concentrates could be sold by the Treadwell company for \$2 per ton, or \$0.05 per unit of sulphur, at a profit of \$20,000 per year to the Company.

By a combination of the iron-oxide contact process with the lead chambers one ton of 40% sulphur will produce 1.88 tons of 50° sulphuric acid, using a combination of fine Herreshoff burners followed by lump burners. Thus, if satisfactory arrangements could not be made with the Treadwell companies, lump pyrites could be used from known deposits on Admiralty island and at Skagway. Such a plant designed to treat 20,000 tons of pyrite yearly should produce 37,600 tons of 50° (Baumé) acid. This acid would contain 20% of sulphur.

Comparing 11c., the unit price of the sulphur on the Pacific Coast used for sulphuric acid manufacture, with 5c., the unit price of local sulphur is equivalent to \$1.20 per ton of acid when making 50° acid. This sulphuric acid from Alaska could afford to pay \$1.20 per ton freight and compete with acid manufactured in San Francisco. No doubt such a freight rate could be obtained from the oil boats which desire a return cargo and also wish sulphuric acid for their own oil refineries. There is no available farm land near Speel river to be injured by fumes. At Speel river sulphuric acid would be used for the manufacture of sodium carbonate, nitric, hydrochloric, and acetic acid.

Sulphuric acid is largely used in the manufacture of blasting powders, some powders requiring as much as 50% acid. In recent years the price of sulphuric acid on the Pacific Coast has been in excess of \$10 per ton. The cost of making 37,600 tons of 50° sulphuric acid at Speel river would be:

| | |
|--|----------|
| Raw materials | \$40,000 |
| Labor and repairs | 12,000 |
| Interest and depreciation, \$100,000 plant at 20%..... | 20,000 |

Total\$72,000

or \$1.92 per ton of 50° acid at Speel river. Allowing a freight rate of \$2 and a selling price of \$10 per ton in San Francisco or Seattle, a profit of \$6.08 per ton or \$228,608 per year would be realized were the whole amount to be marketed for \$10 per ton. The sulphur would be used in the manufacture of wood pulp or combined with phosphates to make fertilizers. Sulphur is also the basis of most chemical industries.

After roasting the 20,000 tons of pyrites for the manufacture of sulphuric acid there would be left 8000 tons of clinkered iron oxide, free from arsenic and lead, containing less than 1.5% sulphur, and less than 0.12% phosphorus. This could be reduced in an electric furnace forming a pig iron that would contain 3% silica and less than 0.02% sulphur.

From the above it may be seen that any development that would deliver during the entire year electric energy to tide water for \$5 per horse-power year is a very attractive undertaking for electro-chemical and industrial purposes. According to the report on Long Lake power development by E. P. Kennedy, 13,000 hp. may be developed at a cost of \$28.36 per horse-power. Allowing 8% interest and depreciation on the plant the cost of producing electric power would be \$3.48 per horse-power year.

Possible Electro-chemical Development, with Costs

Development of Long Lake, 13,540 hp. at \$27.95, \$375,476.

The operating cost of electric plant were:

| | |
|--|----------|
| Interest and depreciation, 8% of cost..... | \$30,030 |
| Operating labor | 6,000 |
| Supplies, etc. | 4,000 |
| General expense and taxes | 6,000 |

Total cost of generating 13,405 hp-year.....\$46,030
Cost of generating 1 hp-year.....\$3.43

Were this power to have a market value of \$10 per horse-power year at Speel river, there would be a profit of \$6.57 per horse-power, or \$88,012, or a profit of 23% on the investment of \$375,476.

Calcium carbide factory, 50 tons daily capacity, capital cost \$300,000.

The cost of producing 16,000 tons of carbide per year would be as follows:

| | |
|--|-----------|
| Interest and depreciation, 10%..... | \$ 30,000 |
| Electric power, 10,660 hp-yr. at \$10..... | 106,000 |
| Lime, 16,000 tons at \$3..... | 48,000 |
| Coke, 9600 tons at \$9..... | 86,400 |
| Electrodes and repairs | 30,000 |
| Labor | 38,000 |
| General expense | 16,000 |

Total cost of producing 16,000 tons.....\$355,000
Cost of producing 1 ton of carbide\$22.20
Cost of containers 4.00
Freight to Pacific Coast ports 4.00

Total\$30.00

Were it possible to sell 16,000 tons of carbide yearly on the Pacific Coast for \$40 per ton there would be a profit of \$160,000 from the carbide plant or a profit

of 53% on an investment of \$300,000. Were the power plant and carbide factory controlled by one company using all the power for manufacturing carbides, the profit would be \$248,012 or 36% on the total investment of \$675,476. Were the carbides marketed at cost, namely \$22.20 at Speel river or \$30 per ton delivered in containers at San Francisco, there would still remain a profit of \$88,012 for the power or 13% on the total investment in power plant and carbide industry. Provided there were no market for the calcium carbide, the whole amount could be converted into calcium cyanamide and from calcium cyanamide into sodium cyanide and ammonium sulphate. The cost of producing calcium cyanamide by combining calcium carbide with nitrogen would be:

Cost of nitrogen plant (including royalties to produce 15 tons of nitrogen daily by the Lunde process), \$100,000.

The operating cost per year, producing 500 tons nitrogen, would be:

| | |
|------------------------------------|----------|
| Interest and depreciation | \$10,000 |
| Operating labor and repair | 10,800 |
| 100 electric hp. year at \$10..... | 1,000 |
| General expense | 5,400 |
| <hr/> | |
| Total | \$27,200 |
| Or \$5.40 per ton of nitrogen. | |

In addition to the nitrogen the above plant would produce 1200 tons of 99% oxygen. Were this utilized the cost of the nitrogen would be less.

Cost of additions to carbide plant to convert 50 tons of carbide to cyanamide daily, \$100,000.

Operating cost per year to produce 17,500 tons of calcium cyanamide:

| | |
|--|-----------|
| Interest and depreciation, 10%..... | \$ 10,000 |
| 16,000 tons of calcium carbide at \$22.20..... | 355,000 |
| 5000 tons of nitrogen at \$5.40 | 27,000 |
| 3000 electric hp. year at \$10..... | 30,000 |
| Labor and repairs at \$5 per ton | 87,500 |
| General expense at \$3 per ton | 52,000 |
| <hr/> | |

Total cost of 17,500 tons calcium cyanamide.\$562,000
Or \$32.17 per ton.

The calcium cyanamide would no doubt be most profitably marketed by conversion into sodium cyanide or ammonium sulphate. Calcium cyanamide treated with superheated steam rapidly liberates all of its nitrogen in the form of ammonia. This ammonia may be absorbed in sulphuric acid, forming a pure ammonium sulphate which finds a ready market at 13c. per pound of nitrogen content when in the form of ammonium sulphate. To convert 17,500 tons of calcium cyanamide into 28,875 tons of ammonium sulphate would require 21,437.5 tons of H₂SO₄. This acid could be manufactured for \$10 per ton at a profit. One ton of calcium cyanamide costing \$40 per ton produces 0.425 ton of ammonia which combines with 1.225 tons H₂SO₄, costing \$12.25 to form 1.65 tons ammonium sulphate having a market value in excess of \$90. To produce 21,437.5 tons of sulphuric acid requires 7000 tons of sulphur which could be supplied from the pyrite now run

to waste at the Treadwell mines. The ammonia obtained from the carbides may be neutralized by nitric acid produced by either the Birkeland & Eyde or Pauling process and marketed at a higher price than any of the other ammonium or nitrate compounds. Such a plant would use the oxygen formed in Lunde machines to enrich the air fed to the Birkeland & Eyde or the Paulding furnaces and increase the output of nitrogen. There would be calcium and carbon left after removing the ammonia from the carbide. This could be used again for the manufacture of carbides.

German Iron Ore Production

The statistics for October 1913 show a surprising advance in the German iron-ore production. Thus, according to data collected by the Association of German Iron and Steel Concerns, the production of iron ore in Germany and Luxemburg amounted to 1,650,205 tons in October, compared with 1,589,197 tons in September 1913 and 1,633,539 tons in October 1912. The daily production in October 1913 amounted to 53,232 tons against 52,973 tons in September 1913 and 52,695 tons in October 1912. The development of the total production during the past two years is shown in the following table:

| | 1913. | 1912. |
|-----------------------|--------|--------|
| January | 1,610 | 1,385 |
| February | 1,493 | 1,320 |
| March | 1,628 | 1,424 |
| April | 1,587 | 1,458 |
| May | 1,642 | 1,492 |
| June | 1,608 | 1,454 |
| July | 1,647 | 1,505 |
| August | 1,639 | 1,527 |
| September | 1,589 | 1,519 |
| October | 1,650 | 1,634 |
| November | | 1,537 |
| December | | 1,566 |
| <hr/> | | |
| Total for year | | 17,853 |
| January-October | 16,094 | 14,749 |

Thus the first ten months of 1913 already showed an increased production of nearly 1,145,000 tons over the same period of the previous year. The production divided among the different classes of the iron industry is as follows, in metric tons:

| | 1912. | 1913. |
|------------------------------------|-----------|-----------|
| Cast iron | 294,727 | 298,828 |
| Bessemer | 31,748 | 31,670 |
| Thomas | 1,062,529 | 1,048,318 |
| Puddled | 44,703 | 38,953 |
| Miscellaneous iron and steel | 199,832 | 232,436 |

Central electric light and power-stations in several states in 1912 were as follows:

| State. | Number. | Generator capacity, kw. | Station output, kw hr. |
|--------------------|---------|-------------------------|------------------------|
| Arizona | 16 | 14,756 | 32,960,084 |
| Connecticut | 44 | 77,655 | 130,672,201 |
| Maine | 79 | 58,757 | 117,092,565 |
| New Mexico | 21 | 7,984 | 9,027,824 |
| Rhode Island | 8 | 38,509 | 62,106,528 |
| Vermont | 61 | 29,468 | 56,552,977 |

Gyratory Versus Jaw Crushers

By C. T. HUTCHINSON

As a rock-breaker is ordinarily considered an integral part of a stamp-milling plant, the question as to the selection of a type of machine is one of the problems confronting the machinery buyer. Rock-breakers as ordinarily manufactured may be broadly classed in two types: the Blake, or oscillating jaw type; and the gyratory. The Blake breaker may be

further subdivided into two types. One advocated by some makers is constructed with sectional frames tied together with heavy steel tie rods which take the strain of crushing and are in tension; other builders advocate the solid one-piece frame in which the frame, including the two sides and the two ends, are cast in one piece. In discussing comparative merits of the two types, it can be said for the former that there is good reason for this method of construction within certain definite limitations. Forged steel is obviously better adapted to withstand a tensile strain than cast iron, as the latter has no elasticity of any consequence and a comparatively low tensile strength per unit of area. In order to manufacture a solid-frame crusher that will render satisfactory service, it is necessary to use a large factor of safety in designing the frame. This results in a very heavy crusher which is difficult to transport and which in case of failure of the frame is very expensive to repair. On the other hand, in constructing a sectional-frame type of machine beyond certain sizes, the mechanical difficulties, in tying the end-frame sections together and keeping them tight and rigid, greatly increase.

With the gyratory type of crusher for small sizes the principal objection is the high first cost as compared to the Blake machine; and also the feed-opening, which is small in proportion to the rated tonnage.

Comparisons of first cost may best be studied by means of curves. Curve sheet No. 1 shows the cost at the factory for all three types of machines. The ordinates represent the area of the feed-opening in square inches and the abscissae represent dollars in first cost at the factory. In studying these curves it will be noted that the gyratory crusher is by far the cheaper in sizes down to the No. 3 machine, which had feed openings 8 by 30 in. and the combined openings 8 by 60 in. The builder's rating for this machine is from 10 to 20 tons per hour, and it is conceded that as far as first cost is concerned the gyratory breaker cannot compete with the Blake below this size. A further reference to sheet No. 1 will show the curve of the solid-frame Blake type machine crossing that of the sectional-frame machine

FIG. 1.

FIG. 2.

at a point that would indicate that, as far as this basis of comparison is concerned, the sectional-frame machine is cheaper in first cost in sizes of about 10 by 16 and smaller. Beyond that point, however, the advantage apparently lies with the solid-frame machine. It is admitted that the most satisfactory basis for comparison would be that of the actual tonnage output, but as this varies so widely in different localities, and as it is obviously most difficult to obtain examples where all three types of machine may be crushing the same rock under exactly the same conditions, this basis of comparison is out of the question. The manufacturer's ratings also vary within wide limits, the difference between the maximum and the minimum given in trade catalogues being in many instances as much as 100%. A comparison by means of the area of the feed-opening is also misleading as giving an advantage to the gyratory to which, in view of the true function of a rock-breaker, it is not entitled.

The object of installing a rock-breaker is to avoid doing by hand what can be done better and more cheaply by machinery, regardless of the theoretical capacity of a breaker which cannot crush a rock that is too large to permit of its entering the feed-opening. For instance, a No. 3 gyratory, as mentioned above, has two feed-openings, each of 8 by 30 in., and is rated at from ten to twenty tons per hour. The area of the feed-opening, therefore, is 240 sq. in. To obtain an equivalent area of feed-opening in the Blake type machine requires one with an opening 12 by 20 in. The manufacturer's rating for this size machine is given at 15 tons per hour. On the other hand, a piece of rock larger than an 8-in. cube would not be taken in a No. 3 gyratory, while the equivalent-by-area Blake machine would take a rock up to 12-in. cubes, or 50% greater than the gyratory. Using the basis of the width of the feed-opening as a means of comparison, the 12 by 20 Blake crusher rated at fifteen tons per hour would be the equivalent of the No. 6 gyratory, which has a combined dimension of feed opening of $12\frac{1}{2}$ by 90 in., a total of 1125 sq. in. The latter machine is rated at from 50 to 80 tons per hour. While there is no doubt that the latter machine would have a capacity within the manufacturer's rating limit on any ordinary rock, it cannot be denied, on the other hand, that if the run of ore from the mine contains any appreciable amount of ore larger than 12-in. cubes, an investment in a machine of this type would not be a wise one.

Curve sheet No. 2 compares the factory cost of the three types of machine as in curve sheet No. 1, except that the ordinates represent the width of feed-opening in inches instead of area of feed-opening. On this basis of comparison, the situation becomes changed, and the gyratory machine will be seen to be the most expensive. The solid-frame Blake crusher curve crosses that of the sectional-frame Blake machine at the 12 by 20 size, thus indicating that below this the 12 by 20 sectional-frame Blake is cheaper, and

above this the solid-frame machine has the advantage.

Reduced to the final analysis, the entire question of the selection of a crusher is an economic one, and the true basis of comparison is one of operating rather than first cost. While exact figures are not available in order that a curve may be plotted depicting the comparative merits of all the types of machine on this basis, it is the consensus of opinion of experienced operators that replacements and renewals may be more easily and more cheaply accomplished with the Blake than with the gyratory. The principal factor influencing the selection of the latter for the great majority of crushing plants having capacity in excess of twenty tons per hour lies in the lower first cost, and the fact that the average run-of-mine rock is of such a size that the greater percentage of it may be taken into a crusher feed-opening 8 in. wide and larger.

It is argued that the expense of an attendant for the crusher is inevitable under any circumstances, and that he will have ample time to break by sledging such pieces of ore as may be too large to be fed directly into the crusher-opening.

The work of plastering Recreation hall, at Lead, is nearly completed, and it is now but a question of a few months when the magnificent structure will be dedicated to the purposes for which it is intended, namely, a clubhouse for Homestake employees. In the building will be installed, in commodious quarters, the Hearst library, a donation of Mrs. Phoebe A. Hearst, which has long been an institution of Lead. The board of directors of the Aid Fund have announced that, beginning with January 1, death benefits will be \$1000 for accidental death and \$800 for death from illness, an increase of \$200 in each case over the amounts which have been paid since the fund was established some three or four years ago. The cash resources of the fund have been constantly growing, and it appears that the increased amount can easily be met from present revenues without embarrassing the fund or levying special assessments. Under the plan of operation of the fund, each employee contributes \$1 per month and the Homestake company not less than \$1000 per month. For all time lost from work, the fund pays the employee \$1 per day, whether he is sick or injured.

The dredging of placer tin in the York district, in the western part of the Seward Peninsula, Alaska, was continued during 1913. Work was also carried on at the lode tin mine on Lost river, in the same district. A small concentrating mill was erected there and some concentrate was shipped. It is reported that there was considerable prospecting for lode tin at Ear mountain, in the north-central part of the peninsula. A little placer tin has been mined which occurs with the auriferous gravels of the Hot Springs district. It is reported that in 1913 lode tin was found in this region, according to Alfred H. Brooks, of the U. S. Geological Survey.

Gold and Silver Movements in 1913

*Although the past year was a highly prosperous one for trade, it was memorable for a combination of circumstances which cast a gloom on markets generally. These include the revolutions in China and Mexico, war in the Balkans, and uncertainty as to the military movements of European powers. Prudence demanded the careful handling of monetary resources, resulting in an unusually high rate for money during the second half of 1913, and a consequent decrease in speculative activity. Nevertheless, the effect of these factors on gold, the basis of international finance, cannot be said to have been very apparent, for with the exception of considerable exports from the United States, in order to pay for securities returned from Europe, no remarkable movements of gold took place as a result of the widespread unrest.

Gold

The gold output of the world was probably £98,000,000 in the past year, a decrease compared with the previous term. A new source of gold supplies is likely to be found in British Guiana. Future prospects of Porcupine, Ontario, are good.

In 1912, India absorbed £27,600,000 in gold, but the net imports in 1913 were only £18,000,000. The Indian people are now disposed to invest in local securities, and a large coinage of new silver rupees was made, and a readjustment of government balances resulted in the decreased gold supplies. The report of the Royal Commission on Indian currency and finance is awaited with interest, as recommendations may be made bearing on the relation between silver and gold in the currency of the country and on the adaptation of the present currency system to the habits of the people, who have lately shown a greater desire for gold. Reserves of gold held by the Indian government are £25,642,000, against £24,820,000, and £13,260,000 at the end of the last three years.

The great state banks of Europe held gold as follows at the close of the last two years:

| | 1913. | 1912. |
|-----------------------|-------------|-------------|
| Great Britain | £33,874,535 | £29,294,455 |
| Austria-Hungary | 51,666,000 | 50,380,000 |
| Belgium | 9,960,000 | 8,559,000 |
| †Denmark | 4,260,000 | 4,305,000 |
| France | 140,696,000 | 128,293,000 |
| Germany | 59,887,000 | 38,504,000 |
| Holland | 12,624,000 | 13,390,000 |
| †Italy | 48,585,000 | 46,019,000 |
| Norway | 2,657,000 | 2,353,000 |
| Russia | 168,355,000 | 155,841,000 |
| Spain | 19,168,000 | 17,485,000 |
| Sweden | 5,672,000 | 5,563,000 |
| Switzerland | 6,813,000 | 7,092,000 |

†It is possible that the figures set against these two banks include a small portion of silver.

[The United States Treasury holds about £260,000,000, while the United States national banks have about £31,000,000 in gold. Australian, including the Commonwealth government reserve, and New Zealand banks hold about £30,000,000.—EDITOR.]

Bar gold maintained the steady price of 77s. 9d. (\$18.66) per ounce.

Germany absorbed a good deal of gold in March, May, June, and September, while Russia was a buyer in October and November. Imports of bar gold to Great Britain in 1913 were £47,137,000 from Africa, India, Australasia, South and Central America, and other smaller countries. Exports totaled £25,477,000 to India, European countries, and £600,000, included in the total, to the United States.

English sovereigns continued to be coined in large numbers. In 1912 the issue in England was 30,248,742; Australia mints, 8,974,401; and Canada, 515; a total of 39,223,658. Only a small proportion remains in Great Britain, the bulk going to India, the British Empire, and foreign countries. The circulation of the English sovereign is extending to most countries, including India, Egypt, Turkey, South American republics, and even the Bank of France makes special efforts to keep a large stock of them in its vaults. The coin has become a handy form of international remittance. The imports and exports of sovereigns in 1913 was £11,947,000 and £19,740,000, respectively. Sovereigns held in the reserves of the Indian note currency at the end of the last year were £21,100,000, against £24,570,000 at the previous period. Owing to the higher rates for money in Europe, there was a falling off in the net export of sovereigns to South and Central America. The low price of coffee and rubber in Brazil had a deterrent effect. Light-weight coins valued at £453,025.5 were sent from India to England. The sweating of gold coins to the lowest weight accepted by the Bank of England is still being illicitly done. Imports and exports of foreign gold coin were £294,000 and £869,000, respectively. A noteworthy feature of the year was the gold exported from New York to France and South America, the net exports from January 1 to December 13, 1913, being £9,000,000.

Silver

During the year 1913, prices were dominated by the operations of the Indian government. Its acquirement of over £6,000,000 in 1912 had imparted strength to the market, which was continued into January 1913 by a further purchase of £1,000,000. Prices on January 7 were the highest for the year, being 29¾d. (\$0.59) per ounce. On account of disappointment in negotiating the Chinese government loan, prices fell away in February. Near the end of that month, a 'squeeze' for delivery in Bombay was manipulated by the Indian Specie Bank, during which operators

caught 'short' were mulcted 7% or 2d. (4c.) on the London price. 'Bear' sales depressed the market in March, forcing almost the lowest figure for the year, $26\frac{1}{16}$ d. (\$0.52). From this point a steady recovery set in, owing to better news from the Balkans, and the hopeful negotiations of the five powers with the Chinese loan. This was floated on May 22, and silver had advanced a fortnight previous to this transaction to $28\frac{3}{16}$ d. (\$0.56). The loan was followed by a dull market, and prices sagged. Supplies were scanty, and a more or less constant demand arose from China in July, improving matters. During the next three months, the Indian government's transactions were felt, there being about £4,500,000 of silver purchased.

The Banks and the Government

Owing to steady withdrawal of all supplies over ordinary market demands, the cash price went to $28\frac{11}{16}$ d. (\$0.57) on September 22. From this date the tendency of prices was downward, and it became evident that trouble was in sight. The Indian Specie Bank had been able to dispose of part of its colossal holding to the Indian government on very favorable terms. The Bank was doubtless more unable than unwilling to sell more before it became too late. Heavy 'bear' sales hastened a fall in prices, and on November 29 the Bank failed. A short account of events leading up to the crisis is of interest: In 1910, Chunilal Saraya, managing director of the Bank, without much difficulty, obtained control of the silver market in India. The time seemed favorable, owing to the likelihood of the Indian government purchases. But having made over-purchases in 1907, the Government delayed taking the step counted on by the speculators. This resulted in the Bank being obliged to acquire more silver to maintain the price of its stock. Gradually the bank's operations became a monopoly in India and London, where the bulk of the stock had to be financed. Then came a duel between the Indian government and the Indian Specie Bank, in which the former was able to acquire silver worth £6,000,000 in 1912, but not from the speculators at the prices they anticipated getting. The Bank was under a big strain, and had to pay as high as $8\frac{1}{2}\%$ interest. Clever attempts were made by the Bank to recoup itself, but without much avail. A heavy bear movement from India set in, prices sagged away, and the Bank could not fulfill its engagements in London. The sudden death of Mr. Saraya completed the debacle and the Indian Specie Bank closed its doors. Prices fell to $25\frac{15}{16}$ d. (\$0.52) on December 1, 1913, the lowest quotation for the year. A strong syndicate, headed by the Hongkong and Shanghai Banking Corporation, and the Chartered Bank of India, Australia, and China, well known in the East, took over the unrealized stock of the defunct Bank. This was followed by a marked improvement in the tone of the silver market.

Stocks at the close of 1913 were as follows: at sea,

2,000,000; Bombay, 1,320,000; London, 15,800,000; and Shanghai, 52,960,000 oz. (including 50,300,000 in sycee or small bars), a total of 72,080,000 ounces.

Imports of silver to England in 1913 were 114,800,000 oz., including 88,300,000 from the United States and Mexico, and 19,600,000 oz. from Canada. Exports were 117,000,000 oz., including 78,000,000 oz. to India, 14,700,000 oz. to Germany, and 6,000,000 oz. to China. The net imports to India on private account were 35,052,341 oz., and 255,814,141 oz. since 1908. Vast sums of money are lying scattered in individual hoards in India, which should be gathered into properly conducted native institutions.

The internal affairs of China, a great silver-consuming country, are full of interest to people connected with silver. When the republic was established in February 1913 it was thought that there would be a wave of prosperity, but due to several movements, the contrary was the case. Instead of silver being freely absorbed by China, the tendency has been for it to move from the interior to the treaty ports. Sycee and big bars in Shanghai, in October 1913, were worth £6,405,000. Imports of silver to Hongkong and Tonkin were £443,650 in 1913. Since the institution of the Chinese Republic, large quantities of notes have been circulated in the country, thereby adding to the currency difficulties.

The Future of Silver

Regarding the future of silver, Samuel Montagu & Co. state that, although industrial consumption must ultimately absorb all surplus silver, prices are unlikely to give way much for that reason. A slight rise in price is not likely, however, to reduce the amount used in the arts, but this means a great deal to the mining industry. The support given to silver on account of Chinese loans has hitherto been fitful and temporary. It is unlikely that China will be a predominant factor in the silver market of 1914. The demand by India, apart from coinage, shows no sign of diminution. The industrial consumption will decrease very little, if at all. The probability of India requiring silver for coinage depends entirely on the monsoon of 1914, and if the harvests are good, the demand will be from £4,000,000 to £5,000,000.

Germany and other European countries will continue to absorb the metal. Mexico will probably use a large quantity for coinage, as was done in 1913. The Mexican silver output in 1914 may be further checked, while Canada will show little, if any, improvement. Mining in the United States of America is on a very sound basis, and the better price level of late has encouraged the mining of lower-grade ores, yet there is no likelihood of an important increase in the current year's silver production. In conclusion, the demand as a whole for 1914 is likely to be good, especially as a large Indian bear is still in existence. Production has little chance of increasing, and the world's apparent stock is considerably reduced.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—To one who has followed the discussions as to the genesis of the gold deposits of the Rand Banket only incidentally to the general study of the problems of ore deposits, C. B. Horwood's articles have a satisfying completeness and their conclusions can be readily accepted on the weight of the detailed evidence so capably assembled. To establish so definitely in the case of the Banket deposits the actual relation in origin of the gold and associated minerals and the dikes which apparently are a comparatively minor feature of the accompanying rock formation, suggests certain interesting analogies and comparisons and may lead to light on the ultimate origin of some of the other 'unique' ore deposits of the world. The Canadian geologists have worked out a similar relation in the explanation of the origin of the silver veins of the Cobalt district of Ontario. These veins occur mainly in a conglomerate (Huronian) and in an inert metamorphic rock (Keewatin). Their origin is now attributed to the direct influence of a diabase 'sill' which was intruded into this formation and furnished the 'mineralizer' for the cracks and fissures in the other rocks.

The same cause is apparently the explanation of the genesis of the rich gold veins in the conglomerate at Kirkland Lake, Ontario. These veins all seem to have a connection in origin with the nearby dikes and masses of syenite, which in this case have a relation similar to the dikes of the Rand Banket and to the sill at Cobalt. The copper in the conglomerate at the Calumet & Hecla mine in Michigan obviously has its origin in the associated eruptive flows, similar to allied deposits in the porous amygdaloidal flows of the same district. At Las Vegas, east of Chihuahua, in Mexico, is a deposit of copper sulphide ore in a tilted sandstone interbedded between slate walls. The genesis of this 'unique' deposit, too, can best be explained by the acceptance of the 'mineralizing' effect of an underlying later eruptive formation. Likewise the real origin of the so-called 'limestone' ore deposits of the Mexican plateau and of southwestern United States is in most cases to be found in the effects of the intrusive rocks invariably accompanying them more or less near. The Silver Reef mine in Utah (silver ore in sandstone) is 'unique' not in origin but only in the locus of the minerals in a sedimentary formation, for the close relationship of the eruptive rocks is here again obvious.

These instances and Mr. Horwood's final solution of

the Banket enigma suggests that perhaps we should not rest with the present accepted origin of some of the other metalliferous deposits. Perhaps the lead and zinc deposits of Missouri and of northern Arkansas may have had their real origin in some deep lying eruptive masses related to the Ozark uplift feature of that region. It is not so easy to suggest the application of the idea to the Wisconsin zinc and lead deposits, but it is conceivable that these, too, had their first origin in deep buried eruptive rocks and that they have wandered through the porous sandstone beds to their present 'habitat' in the limestone formations. May not the real origin of most of the metalliferous ores have been in connection with eruptive manifestations and their present status be due chiefly to the accidental and real influence of the physical and chemical characters of the rocks in which they have finally found a more or less permanent abiding place?

KIRBY THOMAS.

Theory and Practice of Crushing

The Editor:

Sir—In your editorial notes of December 13, under the head of 'Tube-Mill,' referring to the different opinions advanced relative to its practical action, you mention that "theoretical knowledge alone is not sufficient." In this you recall a fact which has recently and forcibly come to my attention in the form of an article in the *Transactions* of the American Institute of Mining Engineers, by Arthur O. Gates, of Lafayette, Indiana, in which he criticizes the inclination of the cones of the Hardinge mill and gives, according to his idea, 'correct' diagrams based upon theories which he probably obtained from text-books. My own paper, read at the February 1913 meeting of the Institute, is the basis for his criticisms. I feel positive that Mr. Gates' theories would be greatly modified could he have the opportunity of practical study and observation of a pebble mill of the Hardinge type, but in order to do this successfully he would doubtless follow my example and discard his textbook and drawing board and resort to overalls, shovel, and screens before deciding as to the line on which the mill should be constructed.

That theoretical knowledge alone is not sufficient, was the basis for the inclination of the cones which form the Hardinge mill, for, as I state in the above mentioned paper, "practice was evolved from practice and not from theory," as the latter did not conform to the former. It is one thing to theorize with the known density of an atmosphere or the gravity of a liquid, and entirely another thing to practice with absolutely unknown qualities, when it will be found that theory and practice not only clash, but often annul expected results. In one case the basis for the theory is a known condition, but these known conditions do not exist in a swirling mass of pebbles of different diameters (consequently surface frictions) operating at different dis-

tances from the periphery in a medium of sand, slime, and water, having densities of vastly varying viscosity. It would be equivalent to an artillerist basing his calculations for a projectile upon the specific gravity of the lead or steel. Certainly even the layman in physics would not expect an ounce of lead in the form of bird shot to be projected the same distance as would an ounce of lead in a bullet, even though the motive force was the same amount of powder. This comparison is not strained, in view of the fact that both cases are dealing with projectiles. The main basis of the results much be considered from a frictional standpoint. We would ask the theorist how much resistance is set up by a 3-in., 2-in., or 1-in. pebble when projected through an unknown quality of frictional interference, and owing to this frictional resistance how far will a given sized pebble be projected by centrifugal force when the pebble is retarded by constantly varying resistances?

The answers would be as various as the problems involved in a pebble mill.

H. W. HARDINGE.

Natomas Consolidated

The Editor:

Sir—Your journal of December 6, 1913, has come to hand, and I notice in your editorial remarks, when discussing Natomas Consolidated of California, that you lapse into an error when you state that the estimate of yield "was made, it is to be noted, not by engineers of the staff, but by a consulting engineer chosen by the London bondholders. It is also fair to recall that the money furnished to the Company was \$2,000,000 less than E. J. de Sabla asked."

It is with reluctance that I take note of your remarks, for when a company is in financial straits, it is not a good time to ventilate private grievances, and the least said, the better it is for the Company, particularly when those who have asked to furnish new money know the facts in question; but I must state that you are in error in both your statements and that your London correspondent has misled you.

Mr. Griffin, the president, frankly summarized for the bondholders the causes which have led to the present financial embarrassment, namely, that the gold dredging fleet was not completed until two years after it was due under the original schedule, and that the burning of one dredge and sinking of three others in addition, curtailed the gold earnings. He further stated that the gold recovery was about 15% less on the gross gold, or about 27% on the net, than the bore-holes indicated; that the cost of the dredges exceeded the estimates by about \$800,000, and that more lands were acquired than was originally contemplated, and that, in consequence of all the present shortage of money resulted.

At the time of the flotation of the 5,000,000 bonds in London, my report on Natomas was published and accompanied the prospectus. As I never made any

estimate of cost of dredges or plant, the excess of cost cannot be laid at my door. It is a matter between the Company engineers and the Bucyrus Co., or Yuba Construction Co. The loss of money through completion of the dredging fleet two years behind the original scheduled time, if blame is to be attached to it, falls on California, London having repeatedly pointed out by correspondence the inevitable consequence which would follow the delay. Regarding the 15% shortage in gross gold recoveries from what the bore-holes indicated, I point out that I checked the report made by the general manager of the Company, and that I stated in my published report that I based my valuation on the average results of the individual values of 1274 drill-holes and test pits, as inscribed on the Company's map.

I stated in the computation of the average values, that I found the Company estimate \$418,000 too large, which I considered a permissible error in so large a gross value as \$28,814,000, which was the Company's estimate, in round numbers, for Natomas Development Co. and Folsom ground. Immediately after this, I added the following sentence, which I copy literally from my report: "The writer wishes to emphasize that, according to the statement of the general manager, Newton Cleaveland, the values of the different bore tests, which are marked on the Company's map, are the original values calculated, reduced by 15%, in order to make them representative of actual extraction. The different test bores are marked on the larger map in places where drilling or shaft sinking took place." My valuation of the Folsom and Natomas ground is conditioned distinctly by the qualification quoted.

As dredging proceeded over a longer period, I was enabled to collect data to check this statement. I then wrote Mr. Griffin that extraction results did not bear out above quoted statement, and I added the extraction results up till then. Mr. Griffin took immediate steps to satisfy himself as to the correctness of my assertion, and from his statement quoted to begin with, it is seen that he admits what I pointed out to him.

CHARLES M. ROLKER.

London, England, December 23, 1913.

A Premature Announcement

The Editor:

Sir—I have noticed frequently of late paragraphs in the newspapers to the effect that I was to take the management of the West Eureka mine, a prospect at Sutter Creek, in Amador county. This is an error, and such publication was made without my knowledge. Moreover, I have no present intention of going to the West Eureka, though I have done some geological and other work for that concern. The object of causing the above-mentioned statement to be published, I can only surmise.

W. H. STORMS.

Berkeley, California, January 21.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Back-gear electric motors of 25 hp. have been installed in the mills of the Homestake company, South Dakota, each driving 10 stamps.

Oregon pine has been largely used for timbering in Broken Hill mines, Australia; but of late there has been a tendency to use an increasing quantity of Australian hardwoods.

The Cathead Gold Mines Co., working near Ararat, Victoria, mined 2790 fathoms of 'wash' during the past half-year, yielding gold worth \$77,000. At one point the profitable gravel is 250 ft. wide. Dividends totaled \$7500. To date the Company has treated 24,226 fathoms, yielding \$893,000, of which \$264,000 was paid in dividends.

Labor conditions in the Joplin district, Missouri, are exceptional, and the work accomplished per man is very high. Miners work 8 hours, and millmen 10 hours, and wages average \$2.72 and \$2.70 per day, respectively. At 57 mines, 2877 men average 5.77 tons per man per day, including all departments, at a cost of 46.8c. per ton mined.

Lightning arresters on the Great Falls smelter stack, Montana, consist of 16 one-inch round copper rods, lead coated for protection against acid, and tipped with platinum points $1\frac{1}{4}$ in. high. The rods are all connected to a copper cable which encircles the chimney a few feet below the top. From this cable, two $\frac{5}{8}$ -in. copper cables lead to the ground on opposite sides of the chimney. The lower end of each cable is fastened to a copper plate about 6 sq. ft. in area, which is buried several feet under ground, and some distance from the foundation, where moisture is usually present. The stack is 506 ft. high, and 50 ft. in diameter at the top.

Diesel engines are gradually being introduced, and there are increases in installations for every purpose. They are internal-combustion engines, and will operate on oil as heavy as 14°B. , with an asphalt or paraffin base, like that from California and Borneo respectively. A recent visitor to San Francisco was the cargo boat *Siam*, of about 9000 tons net register, propelled by Diesel engines. The two screws are driven by two sets of engines of 1600 hp. each. These have 8 cylinders each, 590-mm. diameter and 800-mm. stroke (23.23 and 31.49 in. respectively). The propeller shafts run at 125 r.p.m. The engines are started by compressed air at 20 atmospheres (300 lb. pressure), generated by another Diesel engine and compressor. The compression in the cylinders during

working is 35 atmospheres (525 lb.), and a temperature of 1000°F. is generated. This heat is sufficient to burn the oil fed into the cylinders at 60 atmospheres (900 lb.), no sparking being necessary as in other gas-engines. Oil from Borneo was used on the vessel's trip to San Francisco, but a supply of California oil was taken on before leaving. Oil consumption for the two engines and an auxiliary was about

SHOWING LAY SHAFT OF ONE DIESEL ENGINE ON THE 'SIAM.' THIS SHAFT CARRIES CAMS FOR WORKING VALVE RODS FOR THE CYLINDERS, FOUR RODS TO EACH. THE CAMS ARE FOR MOVING AHEAD OR ASTERN.

20 tons per day, which equals nearly 0.5 lb. per horsepower hour. The fuel cost is 2c. per horsepower day. Exhaust from the main engines is through two 6-in. pipes alongside of one of the masts. Oil storage is 1174 tons, and the steaming radius is $58\frac{1}{2}$ days without replenishing the tanks. Power and light throughout is generated by a 250-hp. Diesel engine coupled direct to a 150-kw. generator, working at 170 r.p.m. A similar engine is used as a standby. The space usually occupied by boilers and coal bunkers in steamers is devoted to cargo on the *Siam*, there being an increase of 15 to 20% in carrying capacity. There are 12 electric winches for hoisting material in and out of the 6 holds. At the Panama-Pacific International Exposition, to be held at San Francisco in 1915, more than 12 large firms have contracted for space in which to install engines constructed on the Diesel principle, in the Palace of Machinery. They will be seen in operation connected to other machinery.

Special Correspondence

JOHANNESBURG, TRANSVAAL

DECREASE OF GOLD IN RAND ORES WITH DEPTH.

A good deal of discussion has been caused in local mining circles by H. H. Webb's report to the Consolidated Gold Fields of South Africa on selective mining; but the admission by the same authority that, so far as the mines of that group were concerned, the average gold content of the ore developed has been decreasing as greater depth was attained, has, although generally recognized, caused no little surprise to be expressed. A short time ago the directors of the Consolidated Gold Fields were highly indignant when one of their engineers made a similar general statement about the Rand, and immediately called upon him to resign, not because the statement was not generally known to be correct, but probably because it was made without first obtaining the usual official permission. There is probably not a single mining group on the Rand which has not suffered considerable disappointment and loss through this decrease of gold content in depth, but none more so, perhaps, than the Consolidated Gold Fields of South Africa, whose misfortune it was to own and control an extensive area in the Germiston district, where even at the outcrop the gold content was below the average of the Rand. Twenty years ago the Simmer & Jack property was recognized as low grade when compared with the Central Rand, and was the first property on the Rand, after its control passed into the hands of the Consolidated Gold Fields, to adopt the big-mill policy which enabled the Simmer & Jack to frequently head the list of gold producers. It was about this time that the value of the deep-level ground began to be recognized. A large area of Germiston ground came within the sphere of influence of the Gold Fields group, and nothing was more natural than that it should fall into its control. That the gold content would decline with depth was not at that time foreseen, because the oxidized zone had not in all cases been passed; but not only has the gold content decreased with depth in this particular area, as in most cases on the Rand, but it has been troubled with more than the usual number of faults and dikes. Still, the Gold Fields, undismayed, continued to open and develop these poor areas, and when the working capital provided proved unequal to the task, the group did not hesitate to raise and guarantee additional debenture capital to complete the development and equipment of these areas. It is doubtful whether any other mining group on the Rand would have displayed the same pluck or gone about the work in such a confident and workmanlike manner; but in those days capital for Rand ventures was easily obtained, and the results should not be judged from today's mining and market conditions. In those days, nothing less than \$10 ore was regarded as profitable, but today the deep-level areas of the Simmer & Jack have made small working profits on ore assaying much less than \$5 per ton. This achievement has not been obtained without the expenditure of considerable working capital in equipment, and perhaps the Simmer Deep will favorably compare in this respect with many better known and more showy mining equipments on the Rand. It is not generally recognized that in these poor deep-level areas, controlled by the Consolidated Gold Fields of South Africa in the neighborhood of Germiston, the working costs compare most favorably with the cheapest worked mines on the Rand. If the Simmer Deep is taken as an example, it must not be forgotten that normal development costs have to be included, while with many of the cheaper worked mines they are either fully developed or the cost of development amounts to a mere trifle per ton. That the Simmer Deep does not earn more than £3000 per month is not due to the higher

cost of deep mining on the Rand, but to the lower gold content of the ore when compared with its richer and outcrop neighbors. Low as the working costs of the Simmer Deep are, the controlling group hopes still to bring them lower by enlarging the scale of working, while the technical advisers express the opinion that working costs will ultimately come down to such a reduced level as will enable these poor deep-levels of the Rand to be worked at a satisfactory profit. Coming from such a quarter as the engineers of the Consolidated Gold Fields, whose experience in working and equipping poor areas on the Rand is unique, such an expression of opinion is valuable, as is also that of the decline of gold content with depth; but the time seems far distant on the Rand when it will be possible to mine and treat \$4 ore from a vertical depth of over 4000 feet.

MAGALIA, CALIFORNIA

DRIFT MINING IN BUTTE COUNTY.—THE ROYAL, STEIFER, DOUBLE EAGLE, INDIAN SPRINGS, SMITH, EMMA, KIRBY, AND MINERAL SLIDE MINES.—SUGGESTIONS FOR FUTURE WORK.

The heavy storms of the past few weeks have resulted in a shut-down of practically all the mines in the Nimshew district, it being cheaper to close and let the surface water run off than to keep them drained. Some damage was done, of course, but this is more than offset by the prospects of one of the best seasons for water in the history of the state. The Royal drift-gravel mine, near Forest Ranch, is employing six men, and a lower adit is being driven to tap the old river channel, known to contain high gold content. The adit will be continued for about 170 ft. to cut the channel at the lowest point. J. W. Chilton, of San Jose, is principal owner, and he and his associates are optimistic regarding the property. The Steifer Mining Co., near Magalia, extension of the old Magalia mine, is now busy constructing its power dam. P. B. Steifer is manager. Ex-Governor Gage and son have the old Springer quartz property under bond and are busy at prospecting work. This property is near De Sabla, Camp One, and has a good record. Mint receipts in the past show over \$7000 in gold recovered from it, and wasteful methods have lost considerably more. The mine has a promising future. Assessment work is finished at the Double Eagle drift-gravel mine, near Berdan. C. D. Campbell and associates, of San Jose, own this property. At the Robbers Roost drift mine, near Nimshew, extension of the Emma drift, five men are working, and driving in gravel is now under way. S. M. Anderson is superintendent.

The Indian Springs drift-gravel mine is to be reopened through the old workings. Disagreement among the owners has kept this famous producer quiet for a long time, but Norman Torrison, the present owner, will soon start operations. It is nine years since the mine has been worked. The published production is \$2,500,000, but men who worked in the mine say that the output was nearer \$4,000,000 in gold. All this was taken out from 4000 ft. of the channel.

The old Smith drift-gravel property, near Lovelock, has been bonded to the Nugget Gravel Mining Co., of San Francisco. The ground is an extension of the famous Indian Springs channel. Development has been done during the past six months, and an electric equipment, consisting of hoist and pump, is now being installed. The gravel taken from this mine so far has averaged over \$6 per yard, and the owners expect a good return on the investment.

In October 1913 Aubrey Rue found a mass of gold and quartz that contained gold worth \$826, in the old Emma mine, near Lovelock. Mr. Rue was just prospecting around in the old workings when he made this pleasant discovery. The Emma is a drift-gravel mine. In fact, this district contains some very famous drift-gravel mines, the Pershbaker or Magalia mine having been the greatest gold-producing drift-gravel mine in the world. Men who worked in this great

mine claim that in the richest part of the channel from \$80 to \$100 could easily be picked up on a shovelful of the gravel. It is reported that this property is again to be opened by a long adit. A large quantity of water flowed from the mine at one time, and the largest pumps in the state were in operation there. A lower adit would thoroughly drain the mine.

The Conger drift-gravel mine, near Nimshew, has just broken into the old Emma workings. Eight men are working, with Mr. Conger as superintendent. O. G. Martin is principal owner. The Kirby mine, in the Nimshew district, now owned by the New Indian Spring Gold Channel Mining Co., has employed six men. The recent storms filled the mine with water, but the Company will start as soon as the surface water has run off. Pay-gravel is being mined. The mine is well equipped with electric machinery, and low costs and high efficiency are maintained. C. G. Kirby is manager. The Loughlin, a promising property on Butte creek, is being operated under bond by G. F. Dyer and new associates.

The Mineral Slide drift-gravel mine, near Magalia, has

IN THE MINERAL SLIDE DRIFT-GRAVEL MINE. WATER IS TAKEN UNDER PRESSURE TO THE WORKINGS, THE GRAVEL WASHED IN THERE AND THEN RUN THROUGH SLUICE-BOXES.

been operated steadily during the past year. Some coarse gold has been recovered, one piece taken out in August last weighing nearly 10 oz. and worth \$182. Last month's storm damaged the flume and ditch to some extent, but these have been repaired. A profitable year is looked forward to by the company. S. P. Moody is superintendent.

A great deal of interest would be taken in this district were it not for the fact that claim-owners, considering the splendid record of the past, put altogether too large a price on their properties. As an old resident of Magalia said: "They want a fellow to come along and fill their hole in the ground with 20-dollar pieces! And if the man has that many 20-dollar pieces he does not want anybody's hole in the ground." It seems to be the difficulty all over the state—the proper valuation of a 'hole in the ground,' of a prospect, and of a mine, and a definite understanding of the term. Capital is naturally against the old methods. It seems that the fairest kind of a deal, and one that is best for all parties, is for an operating company to advance money and the claim-owner to take 10% of the gross output of the mine. Of course, if a company stopped work for any length of time, the mine should revert to the original owner. Another thing concerns the bad condition that titles get into. It would take a 'Philadelphia lawyer' to straighten some of them sufficiently to

risk operating the properties. A mine is never wanted until it has 'proved up,' and then it is always pleasant to find seven or more claimants to it, that you have never been introduced to. A company should protect the title to the property first of all. Miners are an optimistic class, and hard to talk business with. All expense arguments are answered by 'What is going to come out of the mine?' It is time, however, that the old river channels of the Tertiary period were receiving more attention. Over \$300,000,000 has been recovered from them in the past in this state alone.

BRITISH COLUMBIA

THE KAMLOOPS DISTRICT.—IRON MASK MINE DEVELOPMENT.—
WORK AT THE PYTHON, EVENING STAR, AND WHEALTAMER.

In the early nineties, several prospectors located mineral claims on which outcrops of copper-gold ore had been discovered, and about 250 or 300 claims were then taken up within a radius of a few miles of the town of Kamloops. Owing to lack of smelter facilities and the cost of transport, either to the Trail smelter or to the coast, the owners of most of these claims performed sufficient work to entitle them to crown grants or patents, and allowed nearly all the properties to remain idle. The Iron Mask group has been an exception, having been in active operation continuously, with more or less success, since about 1905, when it was acquired by an English corporation. The management attempted to overcome the difficulties of transport costs from the mine to the railroad, thence to the smelter, by erecting a concentrating plant, and later a small matting plant. Neither of these proved quite satisfactory, and the English company, about three years ago, sold out to E. C. Wallinder and associates of Duluth, Minnesota, who formed the Kamloops Copper Co., and in 1912 reopened the mines after a temporary suspension of work for organization and other purposes. The mines are situated on Coal hill, at an elevation of 1600 ft. above Kamloops lake, about six miles southwest from the town of Kamloops, and about $3\frac{1}{2}$ miles from a siding on the Canadian Pacific railway. In order to overcome, as far as possible, the extra costs entailed for fuel for steam, the present management has made a contract with the town for the supply of electricity to drive the recently installed motors for the hoist, pump, concentrating plant, carpenter and machine-shops. An auto-truck, with a capacity of 5 tons of ore or concentrate, has been placed in commission. The concentrating plant has been remodeled, and it is expected will do more satisfactory work in the future. On the Iron Mask claim, a main shaft was sunk 600 ft. by the English company, and all the ore stoped from all levels except between No. 5 and 6. On the Erin claim, one of the group, a shaft had been sunk to a depth of 130 ft. prior to September last, and the ore extracted during development was shipped to the Trail smelter. The orebodies, of which there are several outcropping on the group of claims which embrace, in the aggregate, an area of about 600 acres, occur as veins in diabase country rock. The vein-filling is composed of copper carbonate and some bornite and chalcopyrite, usually associated with magnetite as the matrix, having an average value of about 6% copper, with low gold and silver content. The depth to which oxidation has extended varies, but usually is about 150 ft. below the surface. The extent of the various orebodies has not been fully determined except in one shoot on the Iron Mask, which is about 200 ft. long and from 4 to 20 ft. wide, but at the greatest width the ore is lower grade, and for treating this the concentrating plant was installed. The management proposes an energetic policy in future with regard to mining operations, and expects to decrease the cost of production and haulage considerably below what it was prior to the present year.

No other property in this copper belt is being operated at

present, but there are about a dozen claims in addition to the Iron Mask group on which prospects are sufficiently promising to warrant more thorough development, providing cheap haulage to the railway and fuel for driving machinery can be obtained. At some of these claims, notably on the Python, Evening Star, and Whealtamer, considerable development has been done, and a large tonnage of low-grade oxidized copper ore has been opened.

NEW YORK

BUSINESS CONDITIONS AND NEW BOND ISSUES.—THE COPPER MARKET AND VIEWS OF CONSUMERS.—FEDERAL MINING & SMELTING, BATOPILAS, AND HOMESTAKE.—MINING AT COBALT.

There has been a good deal of optimism regarding the outlook for business since the first of the year, but the strongest kind of evidence of an actual basis for optimism was disclosed last week. The state of New York has issued \$51,000,000 in 4½% bonds for the construction of canals and roads. These were advertised in the usual way, and a syndicate composed of W. A. Read & Co. (a bond house) and Kuhn, Loeb & Co. secured the entire issue on a bid of 106.077. When the syndicate put the bonds on public sale at 107½, the issue was oversubscribed twice over, and the syndicate in about two hours made a profit of \$550,000 on the transaction. No evidence could be clearer that plenty of money is available for well secured investment, and that the financial position is fundamentally sound.

The future of the copper market is naturally a never failing source of interest to all copper producers, and the opinion of large consumers is of much interest because of the point of view. The National Conduit & Cable Co. is a large user of the metal, and it is worth while to reproduce the views which it expresses in a recent circular:

"The new year began with material changes in the copper situation, and developments during the next few months will be watched with peculiar interest. The last half of December witnessed a firmer market for copper as the result of some important sales made to European buyers. Dealings were in large volume, especially with foreign interests, and a fair degree of activity extended to domestic manufacturers. London dealers and operators were prominent in the recent movement which lifted prices of electrolytic copper from 14¼ to 15c. It soon became evident, however, that consumptive demand did not warrant the rise in prices engineered in the closing weeks of last year, and early in the present month the market began to show a sagging tendency.

"Although domestic consumption at present is much below capacity, there is no reason to expect that it will remain at the low level represented by last month's deliveries. We fully expect to see larger quantities of copper going into home consumption each month before long, and in the coming weeks we look for more active buying. It is not probable, however, that manufacturing activity will be immediately resumed at approximately full capacity, but it is reasonable to assume that consumption will gradually reach a more normal basis within the first half of this calendar year, provided fundamental conditions are favorable."

Another consumer believes that stocks here are being kept low to bolster the market and expresses himself as follows:

"We have had to pay 14½ to 14¾c. for electrolytic over the past few days. The strength of copper prices is due to heavy shipments of copper to Europe. This country is exporting more copper than ever before in its history, notwithstanding a substantial falling off in consumption in Germany, Great Britain, and France. Exports so far this month are at the rate of nearly 1,000,000,000 lb. per year. Consumers are not able to reconcile these large shipments with industrial conditions abroad, but one thing is certain, they are not allowing large stocks of copper to accumulate in this country. They are shipping it almost as fast as it is produced and in this way

the agencies are in a position to mark up the price of the metal."

The Federal Mining & Smelting preferred stock was a source of much interest last week, since it suddenly advanced from 35¾ to 40 on sales of 1600 shares. As nearly all the preferred is in the hands of people who hold less than 50 shares, naturally everyone was keen to know what had happened. At the time of writing the mystery has not been solved. The Wettlauffer-Lorrain has made its report for 1913, showing a net profit on its operations of \$38,042. As dividends amounting to \$141,659 were paid there was a considerable deficit for the year, cutting down the company's surplus to \$156,124. The Batopilas Mining Co. did better with a total of \$742,568 income and a net profit of \$160,094. The Company has a surplus of \$3,219,816. The Homestake makes a new record, even for itself, having paid \$2,167,620 in cash dividends and a 15% stock dividend. The new stock represents \$3,000,000 which has been put into new construction and equipment during recent years.

Cobalt mines continue to be favorites in the New York share market and the large dividends which many of them pay furnish an excellent atmosphere in which to foster the growth of new enterprises. Thus the Nipissing Mines has just paid dividend No. 32, which brings the total to date to \$11,340,000, or nearly 200% on its capitalization. Crown Reserve has paid \$5,508,290 to date and is paying at the rate of 2% per month. The production is showing a decrease from 1912, when it was 3,430,900 oz. of silver, but much is hoped for from the five acres of ground made available by the draining of Kerr lake, which is counted on to yield 51,000,000 oz. Crown Reserve has another string to its bow in the McEneaney mine at Porcupine, which it has re-christened the Porcupine Crown, since acquiring it in 1911. A 20-stamp mill has been built and much is expected from this promising property.

TORONTO, CANADA

HOLLINGER DEVELOPMENT.—DOME RETURNS.—DOME LAKE CAPITAL.—COBALT ORES TO ENGLAND, GERMANY, AND THE UNITED STATES.—SILVER QUEEN MINE.

The Hollinger mine has recently considerably improved underground. The winze from the 425-ft. level of No. 4 vein has reached a vertical depth of 550 ft., at which point a station will be cut and a new drift driven. The directors have inspected the mine and decided to start diamond-drilling to a depth of 3000 feet. A large increase in the capacity of the mill is under consideration, and will probably be undertaken in the near future. Results at the Dome in December show a slight falling off, the tonnage milled amounting to 13,470 and the gold production to \$106,904, as compared with 13,820 tons and \$121,150 in November. The directors of the Dome Lake have decided to increase the capital from \$750,000 to \$1,000,000, and the shareholders will be asked to ratify the increase at a meeting to be held on February 9.

Cobalt ores are finding a market in England and Germany, several shipments having recently been made to Birmingham, Manchester, and Hamburg. The Crown Reserve has a contract for consignment of high-grade ore to the last port. Ores having a high cobalt content are also becoming marketable to advantage, the Nipissing having recently shipped two carloads to England and one to the United States. At the Silver Queen, now operated by the Aladdin-Cobalt under lease, an ore-shoot 6 in. wide and 30 ft. long, containing 1400 oz. ore, which had been overlooked in former operations, has been discovered and is being stoped. The Aladdin-Cobalt, which has now a controlling interest in the Chambers-Ferland, has made an offer to buy out the stockholders of that Company by giving them one \$5 share of Aladdin stock for every 20 shares of Chambers-Ferland. The Coniagas has declared its regular quarterly dividend of 6%, with an additional 3% bonus, which brings the total returns to shareholders up to \$6,080,000.

General Mining News

ALASKA

By a vote of 46 to 16 the United States Senate passed, on January 24, the Alaska railway bill, directing the President to purchase or construct 1000 miles of railroad in Alaska at a cost not to exceed \$40,000,000.

JUNEAU

December results from the three companies operating on Douglas island were as follows:

| | Alaska Mexican. | Alaska Treadwell. | Alaska United. |
|---|--------------------|----------------------|-------------------|
| Development, feet | | 108 | 1,185 |
| Ore in stopes, decrease or increase, tons | +1,417 | -53,529 | -5,955 |
| Stamps working | 120 | 540 | 240 |
| Ore crushed, tons | 19,758 | 80,094 | 37,912 |
| Gold by amalgamation..... | \$21,771 | \$119,165 | \$41,919 |
| Gold from concentrate | 23,159 | 99,809 | 30,048 |
| Realizable value | 44,480 | 216,784 | 71,248 |
| Yield of ore treated, per ton.. | 2.27 | 2.73 | 1.90 |
| Operating expenses | 23,106 | 82,739 | 49,560 |
| Construction | 5,207 | 27,146 | 8,230 |
| Estimated net profit | 16,167 | 106,899 | 13,456 |

KETCHIKAN

Litigation has resulted in the old Cymru copper mine, known as the North Arm, situated at the head of the north arm of Maori sound, being shut down since 1907; but it was recently bonded to a local company formed by G. V. Bland, W. P. Powers, and others. The property is equipped with a Fairbanks-Morse compressor, 4200 ft. of surface tram, and orebins. Two shafts are down 95 and 105 ft., respectively. A good deal of surface mining has been done. In 1906, 3000 tons of ore sent to a smelter averaged 4.5% copper and \$1.25 per ton in gold and silver. Work is to be started at once, and shipments made in April.

ARIZONA

COCHISE COUNTY

The Hermitage company's 50-ton mill, 7 miles south of Hereford, is in operation. Two Harz jigs are included in the plant. The Hermitage Mining Co. is composed of Memphis, Tennessee, people, and John Moffett is manager. There are 144 Holquist patent machine-drills working in the Warren district, made by the Cochise Machine Co. Results are said to be quite satisfactory. The ore from the mines contains lead, zinc, and silver.

GILA COUNTY

(Telegraphic Correspondence.)—A contract has been let to the American Bridge Co. for the erection of a smelting plant for the International Smelting & Refining Co. The cost will be over \$2,000,000.

Miami, January 28.

(Special Correspondence.)—Extensive development continues at the Inspiration. Part of the Joe Bush ore dump is ready for caving. The Scorpion hoist is hauling about 700 tons of ore per day at present. During the first fortnight of January, 2000 tons came through this shaft, 8500 tons of ore and waste through the Colorado shaft, and 4600 tons of waste through the incline shaft. This material came from 2700 ft. of development. The flotation plant is working full time, and an Oliver filter is being tried, while a Trent filter is being erected. Other filters may be tested for their suitability in this treatment. The usual construction work is going on at the concentrating plant. The International Smelting

& Refining Co. is receiving bids for steel work for the smelter as well as for a power-station.

Miami, January 17.

(Special Correspondence.)—Ore from the Superior & Boston now averages between 7 and 8% copper. The faulted vein has been found 210 ft. from the fault, where it is 30 ft. wide, 3 ft. being good ore. Cross-cutting is under way on No. 13 and 14 levels of the Arizona Commercial. It is intended to bail the water flowing from the 1200-ft. level, after it flows down the shaft. High-grade ore is still being shipped from stopes above 650 ft. in the Iron Cap. For a width of 10 ft. and 75 ft. in length the stope has averaged about 20% copper and 31 oz. silver. In 1913 development totaled 1610 ft., and 4899 tons of ore yielded 763,882 lb. of copper. Revenue was \$91,814, and profit \$38,460. The annual meeting was held at Portland, Maine, on January 6, 1914.

Globe, January 17.

MARICOPA COUNTY

Negotiations for the sale of the claims of the Sunflower Cinnabar Mining Co., 75 miles northeast of Phoenix, have fallen through, and the Company, composed of Phoenix people, will operate the property for itself. Probably a 50-ton plant will be erected to replace the present 10-ton installation. Robert Scott, the mercury furnace inventor, has just examined the Sunflower group.

YAVAPAI COUNTY

The Humboldt smelter is not working at present, but the mill is producing concentrate for the Hayden smelter. A new reverberatory furnace is being constructed at the Humboldt, and a flotation plant will soon be at work. Development at the Baumann copper mine is promising. The Cherry Creek Mines Co. is diamond-drilling at Cherry. At the Poorman mine, in the Walker district, a hoist is being installed to unwater the shaft.

CALIFORNIA

AMADOR COUNTY

The South Eureka Mining Co. paid \$251,000 in dividends in 1913, making a total of about \$740,000 since the Company was formed. The South Eureka owns the Oneida mine, and two

SOUTH EUREKA MINE AND MILL.

stamp-mills are operated. The Zeila mine is being sampled by B. M. Lynder, of Los Angeles, Robert E. Cranston and Alex. Nise of San Francisco, and R. H. Elliot of Berkeley. The new shoot at 1500 ft. is being carefully examined.

ELDORADO COUNTY

(Special Correspondence.)—The Central El Dorado Gold Mining Co. is developing the Davidson mine, in the Mud Springs district. It has also acquired adjoining claims called the Three Champenoise mines. The old workings, which proved profitable for the owners thirty or forty years ago, have been reopened and found to consist of a 400-ft. adit, with stopes and an incline shaft 300 ft. deep with a few hundred feet of drifts. Since then an incline shaft has been sunk 300 ft. on the west vein. At 200 ft., 3 ft. of ore gave

satisfactory results in the mill. This was also good at 250 ft., and 500 ft. of drifts have been driven at the 300-ft. level. The mill returns at this depth were \$3 per ton. Active work will be started again in the spring. The property is equipped with an 80-hp. oil-burning boiler, 25-hp. hoist, 35-hp. compressor, five 1000-lb. stamps driven by steam, assay office, and all necessary appliances to make the plant as complete as possible. Water power was installed a year ago, and a change was made in driving machinery from steam to water. Rene Bordier is manager, and George Blanchin and M. Bordier in France are heavily interested. It is probable that additional stamps and concentrators will be erected during the current year.

Eldorado, January 19.

E. E. Shook, agent for the Placer County Properties Co., was recently at Placerville with a view to locating and obtaining control of all the magnesite and asbestos deposits in the county.

NEVADA COUNTY

A 40-hp. electric triplex pump is being installed at the 1000-ft. level of the Oustomah mine. When this is working, the shaft will be sunk to 1200 ft. The mill is kept busy on ore from the 600-ft. level. E. C. Klinker, the superintendent, has resigned to take charge of the Eagle Bird and Fritz Meister mines, near Washington, in this county. The Oustomah offices are to be moved from Los Angeles to Nevada City. Diamond-drilling drift-gravel areas on Columbia hill by F. S. and F. M. Phelps has defined the extent of the gravel, and an adit will be driven in the spring to get under the channel.

PLUMAS COUNTY

Six claims, containing good ore, have been located two miles from Quincy by A. D. Le Roy and J. B. Gillespie. Bad weather has caused a stoppage of work in the district.

SACRAMENTO COUNTY

Gold produced by the Natomas Consolidated's 10 dredges at Natoma, and 3 at Oroville during 1913, amounted to \$2,299,260, against \$2,020,634 in 1912, and \$2,053,593 in 1911. The net profits over bond interest are over \$300,000.

SHASTA COUNTY

A two days' trial of the Hall process at the Coram smelter has proved satisfactory. The Balaklala sampling works was burned on January 21, the loss being \$25,000. The Hall plant was not damaged. Storms have interfered with the electric-power service. Ore from the Balaklala mine is being sent to the Mammoth and Mason Valley smelters. The Mammoth Copper Co. has 50 men employed at the Stowell claims, and at all mines and the smelter 910 men are busy. The monthly payroll is about \$100,000.

SIERRA COUNTY

The interior shaft being sunk from No. 4 adit of the Plumbago mine has cut 4 to 6 ft. of ore containing free gold and rich arsenical pyrite. About 40 men are employed about the mine and 20-stamp mill.

A new adit will be driven at the Mountain House drift mine, to open the gravel, the present workings being too high. The adit will be 500 ft. long. Shaw brothers, of Oakland, are working the property. East of the Kate Hardy mine, R. D. Norris has staked two claims on a vein outcropping on Oregon creek.

SISKIYOU COUNTY

At the Hardscrabble mine, the cross-cut adit has cut 12 ft. of mineralized rock, and it is figured that the main vein will soon be cut. The Company will install an electric power-plant, machine-drills, and a stamp-mill.

TUOLUMNE COUNTY

(Special Correspondence.)—The complete unwatering of the Dutch mines shows that 300 ft. of unexplored ground

remains between the 1500 and 1800-ft. levels, and the management has decided not to sink the shaft below its present depth until drifts have been extended into the undeveloped orebodies. The Columbus mine, one mile north of Tuolumne, is being unwatered preparatory to the resumption of operations by a new company. T. G. Winwood will be in charge as superintendent. Ten new cottages have been erected at the Shawmut mine. The shaft at the Black Oak, 1700 ft. deep, is being sunk 200 ft. A large electric pump is being installed in the mine. It is expected that New York and Philadelphia capitalists will shortly reopen the Seminole and Mayflower mines, near Tuolumne.

Sonora, January 24.

COLORADO

CLEAR CREEK COUNTY

The mills in the Idaho Springs district are kept fully employed. Thirty men are at the Combination plant, which is treating ore from the Saratoga. The Jackson mill is treating custom ore, and from the Golden Eagle and Bride mines. E. F. Gustafson has leased this mill.

GUNNISON COUNTY

A revival of mining at Crested Butte, and the opening of a considerable quantity of lead ores, has started some discussion as to the feasibility of smelting in that district. Transport to distant smelters is costly, while coke is made nearby.

LA PLATA COUNTY

Rich gold and silver ore has been discovered by D. Cason, two miles from Needleton, and 33 miles from Durango, at a height of 9500 ft. above sea-level. The mine shows 18 in. of high-grade and 6 ft. of low-grade ore.

MONTROSE COUNTY

(Special Correspondence.)—This place is the centre of the Paradox district, which is known for its uranium ores. As the mining for this ore is mostly at the surface, and the ground is frozen at present, there is not as much work being done as usual. Indications point to a greater output during the current year than any previous period.

Bedrock, January 12.

SUMMIT COUNTY

During the week ended January 10, the Tonopah Mining Co. completed its purchase of the property of the Reliance Gold Dredging Co. at Breckenridge. This included 30,000 acres of placer ground, a fine machine-shop, and three dredges. B. Stanley Revett is to be resident manager.

TELLER COUNTY (CRIPPLE CREEK)

(Special Correspondence.)—Proposals from contractors are desired for building to specifications, in whole or in part, a 300-ton mill for the El Oro M. & M. Co., Elkton, Colorado. The work will be under the direction of William H. Kritzer, superintendent, and, weather permitting, construction is to begin in March.

Cripple Creek, January 22.

The Golden Cycle company has resumed sinking its main shaft near Goldfield from 1700 to 1900 ft. The shaft collar is 10,066 ft. above sea-level. The Vindicator main shaft will also be deepened from 1600 to 1800 ft. This shaft collar is 10,209 ft. above sea-level. A Fairbanks-Morse pump, of 200 gal. capacity per minute, has been installed on the 500-ft. level of the El Oro company's Eclipse shaft. On No. 9 level of the Mary McKinney, the ore-shoot has been opened for 300 ft., it being 10 ft. wide and yields up to \$30 per ton. A dividend, equal to \$26,184 was paid on January 24. A new set of rolls from the Colorado Iron Works is being installed in the Rex mill. A lease has been taken on the Pharmacist dumps, the ore to be treated in the Rex plant. The Kavanaugh mill is working full time. Rich ore is still

being mined from the 400-ft. level of the W. P. H. mine, worked by lessees. At 1350 ft. depth in the Granite a cross-cut has intersected the main Granite vein, where the ore contains sylvanite, calaverite, and iron pyrite containing 5 oz. gold per ton.

IDAHO

Mining men who have spent some time in the Sawtooth mountains, during the past few summers, state that there are good chances for prospectors in the region. The range lies partly in Boise, Blaine, Custer, and Elmore counties. The snow is deep in winter, and little can be done with the present state of transport.

According to Stanly A. Easton, manager of the Bunker Hill & Sullivan company at Kellogg, the draft of the workmen's compensation act being discussed at Boise has apparently met the approval of all interests.

CUSTER COUNTY

Near the town of Custer, the Bonanza Gold Mining Co., composed of Salt Lake City people, has been pushing development until the winter set in. About 400 ft. of work has opened a wide decomposed vein of ore worth \$10 per ton. A 40-ton mill was completed just before winter. It is driven by a Dubois gasoline engine. Near the Bonanza is the Wall Street property, containing gravel and lode claims. A large dam is being constructed for hydraulicking.

SHOSHONE COUNTY

The Stewart Mining Co. reports that the gross value of mine and mill products for the last quarter of 1913 was \$325,866. Deducting all expenses, including development, the net income was \$177,942. No. 2 dividend of 10% and an extra one of 2½% was paid on October 3, while No. 3 of 10% was paid on December 29. Cash at the end of 1913 was \$342,650. The Hecla Mining Co., of Burke, has paid its first monthly dividend of 2c. per share for the year. This makes \$20,000, and \$2,990,000 to date.

The raise connecting the lower and upper workings of the National mine at Mullan has been completed, and the upper workings, a 200-ft. shaft, and numerous stopes, filled with water, were drained through the raise and the long lower adit, which is practically a mile long. With the completion of the raise, the Company will cut stations every 100 ft., from which ore will be mined. The new mill is fast nearing completion, and, if delayed shipments of machinery are received in the near future, it is expected that the National will be ready for active operations early in February. The motor tram from the mine to the mill, a distance of nearly two miles, has been completed and is ready for service.

MONTANA

JEFFERSON COUNTY

(Special Correspondence.)—Lessees at the Baltimore mine, near Boulder, are shipping a mixed sulphide ore, carrying 25 oz. silver, 7% lead, 2% copper, and \$2 in gold. At present the stoping width is 5 feet.

Boulder, January 24.

LEWIS AND CLARK COUNTY

Work being done by E. R. Purnell in the Scratch Gravel hills is opening good silver, copper, and lead ore, and prospects are encouraging. The property of the Copper-Montana Silver Mining Co. is situated six miles north of Helena.

NEVADA

CHURCHILL COUNTY

During December the Nevada Hills Mining Co. treated 4140 tons of ore averaging \$10.27 at a cost of \$7.45 per ton. The loss in tailing was \$1.52 per ton. Net returns were \$5401. Cash on hand and in banks at the end of 1913 was \$110,618; supplies, \$43,600; concentrate and bullion in transit, \$11,820; and metals in solution, \$20,000. The annual meeting of the Company was held on January 23.

CLARK COUNTY

The Good Springs Anchor Co. has been organized with Frank A. Keith president and manager, Seeley W. Mudd vice-president, and R. I. Rogers, Phillip Wiseman, and J. W. Keith directors, to develop and operate a zinc mine in the Good Springs, Nevada, district. The mine is eight miles from Jean, on the Salt Lake road, and an 1800-ft. aerial tramway and other equipment has been ordered. A contract has been made with the Empire Zinc Co. for two years for shipments at the rate of 10 tons per day. Based upon 40% zinc concentrate, the price at Jean nets \$16.90 per ton, from which is to be deducted mining, estimated at \$3, and hauling at \$2. On the 132-ft. level samples cut in 5-ft. sections in a 30-ft. cross-cut gave the following results:

| Silver, oz. | Zinc, %. |
|-------------|----------|
| 6.0 | 34.5 |
| 5.6 | 46.9 |
| 2.0 | 45.8 |
| 1.0 | 31.1 |
| 3.6 | 13.4 |
| 3.0 | 11.8 |

A variable amount of lead is also found in the ore.

ELKO COUNTY

According to J. C. Griffen, Jarbidge is improving. A 10-stamp mill is being erected at the Flaxey mine, and 30 stamps are working at the Alpha, owned by Chicago people. Owing to high transport charges, only rich ore can be shipped from the camp. The Bluster mine has a shipment of \$100 to \$150 ore ready. This was mined at 300 ft., where the vein is 4½ ft. wide for 225 ft. in length, worth \$19 per ton. A mill may be erected in the spring.

ESMERALDA COUNTY

The Goldfield Consolidated mine produced 28,804 tons of ore during December, giving a net realization of \$153,353. Costs totaled \$6.46 per ton. Development covered 3071 ft. at a cost of \$4.53 per foot. On the new No. 1 level of the Sheets-Ish area of the Mohawk, the 3-D sill produced 272 tons of \$40 ore. The 815 drift of the Grizzly Bear produced 75 tons of \$16 shipping ore. The mill was run to full capacity throughout the month, without drawing heavily on second-class dumps, but the average grade of the ore was low.

Great interest is being taken in the Florence mine, where from 8 to 18 in. of rich ore was cut in an incline raise above the 350-ft. level. This has since been opened 40 and 50 ft. northwest and southeast, respectively. A winze from the 250-ft. level is down 18 ft. in 3 ft. of ore worth \$96 per ton, and will be sunk to meet the raise from 350 ft. Ore worth \$20 to \$30 is being shipped to the mill. At a depth of 650 ft. the Oro shaft has got into broken vein formation. A station has been cut at 550 ft., and the pumps are handling the water with ease. The Silver Pick shaft is down 485 ft., and has opened a vein for over 80 ft., assaying from \$2 to \$10 per ton. A station is to be cut and extensive development done. A larger ventilating plant is being installed at the Merger for this and the Atlanta mines. The temperature at 1750 ft. is very high.

EUREKA COUNTY

(Special Correspondence.)—It is stated that a company under the management of Mr. Berardi, is constructing a 50-stamp mill at Mill cañon, a short distance from Beowawe.

Beowawe, January 23.

HUMBOLDT COUNTY

Seattle men, headed by Charles G. Heifner, have taken an option on the Kramer Hill mine, near Golconda. The purchase price is said to be \$350,000, and the buyers have 90 days in which to sample and make mill tests of the ore opened. If satisfactory, a large mill will be erected. Butte men have taken an option on the Elko Prince. They have

already spent about \$60,000 on the property. Rich ore is being shipped from the Seven Troughs mine. There is 2500 tons of \$30 ore on the Delaware dump, and about 30,000 tons blocked out in the mine. At present there are about 100 men employed at Seven Troughs. A road is being constructed to the cinnabar property of C. E. Dolbear, 22 miles south of Lovelock, and a retort is being installed to treat the ore. This was made by the Joshua Hendy Iron Works of San Francisco.

LANDER COUNTY

(Special Correspondence.)—The Austin Manhattan Mining Co.'s property at Austin was sold by auction recently, to Pittsburgh interests. The Mariposa Mining Co., whose mine and plant is situated at New York cañon, near Austin, is completely closed down after operating its new mill for six weeks. Austin, January 23.

MINERAL COUNTY

(Special Correspondence.)—A little activity is apparent at Gold Dyke, where several prospectors are working in a small way. Small shipments of copper ore continue to be made from Luning to the Mason Valley smelter at Wabuska.

Luning, January 23.

NYE COUNTY

(Special Correspondence.)—The Nevada Cinnabar Co., at Ione, is continuing construction work through the winter under the direction of Mr. Pearce, who was for many years connected with the Quicksilver Mining Co. at New Almaden, California. The plant will be complete in every detail. The ore will be dried in a rotary machine and elevated to a 50-ton storage bin on top of the 50-ton Mirabel-type Scott furnace.

Ione, January 23.

Snowstorms and slides of ground have interrupted the electric-power service to the mining districts of the county.

STOREY COUNTY

A heavy snowstorm caused a considerable amount of inconvenience at Virginia City during the past week. The water in the Con. Virginia winze was only 3 ft. above the 2700-ft. level on January 29.

WHITE PINE COUNTY

No. 6 steam-shovel, at Copper Flat, was being moved to a

COPPER FLAT, ELY, NEVADA.

new position recently, when it partly turned over, injuring four men in charge of it.

Reports filed with the county assessor for the last quarter of 1913, in compliance with the bullion tax law, show the following results:

| | Nevada Con. | Giroux Con. |
|-----------------------------|-------------|-------------|
| Ore mined, tons | 848,826 | 38,916 |
| Gross value of metals | \$2,984,867 | \$78,019 |
| Mining cost | 558,484 | 29,261 |
| Transport | 228,553 | 13,273 |
| Treatment | 1,513,569 | 54,375 |

| | | |
|-----------------------------|---------|---------------|
| Net profit | 684,261 | |
| Bullion tax on profit | 14,780 | (loss) 18,890 |

NORTH CAROLINA

MONTGOMERY COUNTY

(Special Correspondence.)—The mill of the Uwarra Mining Co. is now in operation, and an excellent extraction is reported. Candor, January 26.

OREGON

BAKER COUNTY

Eighty acres of ground near Sumpter was sold by N. Hatley for \$6000 to the Powder River Dredging Co. The greater part of this area includes creek gravels.

JOSEPHINE COUNTY

The organizing of a mining experiment station at Grant's Pass is being discussed in Congress at Washington, the bill having been introduced by Mr. Hawley. It provides that the station be under the control of the Bureau of Mines, the appropriation necessary being \$25,000. A survey of the Dothan quadrangle is also suggested.

SOUTH DAKOTA

LAWRENCE COUNTY

A statement regarding the Homestake Mining Co.'s employees' aid fund showed the following position at the end of 1913:

| | | | |
|-------------------------|----------|-------------------------|----------|
| Bal. at Dec. 31, 1912.. | \$23,338 | Death benefits, 1913.. | \$16,000 |
| Employees' contribu- | | Injury benefits, 1913.. | 9,691 |
| tion in 1913..... | 27,584 | Sick benefits, 1913.... | 7,921 |
| Homestake Co. contri- | | Insane benefits, 1913.. | 200 |
| bution in 1913..... | 12,000 | Bal. at Dec. 31, 1913.. | 30,035 |
| Interest, etc. | 925 | | |
| Total | \$63,847 | Total | \$63,847 |

There is promise of considerable activity in the Tinton district this year.

UTAH

JUAB COUNTY

The following table shows results of operation at the Iron Blossom mine during the past year:

| | |
|---|-------------|
| Development, feet | 6,080 |
| Cost per foot | \$6.06 |
| Ore mined, dry tons | 39,526 |
| Metals produced: | |

The Lower Mammoth Mining Co.'s report for 1913 contains the following information: The past year's work in new ground has been unsatisfactory, the orebodies being low grade. This was especially so at 1800 and 2000 ft. The Gold Chain company is extending work in its property from 1500 and 1800 ft. in the Lower Mammoth. The general manager suggests further prospecting, although the directors have considered the question of shutting down. Copper ore shipped was 101 tons, worth \$979; zinc ore, 806 tons, worth \$9673; and lead ore, 68 tons, worth \$89. Total receipts, including an assessment of \$10,000, were \$22,901. The expenditure was \$26,326. Cash on hand at January 2, 1913, was \$1162.

During 1913, a total of 6383 ft. of development was done in

the Chief Consolidated, making 23,000 ft. to date. On February 2 a dividend of \$43,822 was distributed by the Company.

PIUTE COUNTY

New York people have leased and bonded, with a purchase option, the Glen Eyrie, Cascade, Shamrock, Roosevelt, Taft, and Deseret groups of claims in Bullion Creek cañon, seven miles southwest of Marysville. These claims cover over 1000 acres. The Bully Boy, adjoining, may be included in the deal. It has produced between \$400,000 and \$500,000. A 100-ton mill was erected there last year. Several long adits have been driven in the leased properties, and the ores contain lead, silver, copper, and gold. Men have already started work here, and a large number is expected by May.

SALT LAKE COUNTY

The Alta Tunnel & Transportation Co.'s tunnel was in 444 ft. last week in blue limestone. The face of the drift was streaked with stringers of manganese, which is often associated with ore in the Wasatch range. It is hoped that the work will cut all the veins in the Alta district, within a total length of about one mile. F. V. Bodfish is president of the Company, and Roy L. Mack is superintendent. Two Austrian miners were imprisoned in the Boston part of the Utah Copper Co.'s mines last week by a fire in the hoisting shaft. Three other Austrian miners made an attempt at rescue, but lost their lives as a result. Oxygen helmets were used later by L. W. Anderson, mine superintendent, J. T. Bowen, and Julius Sorensen, of Salt Lake City. They were assisted by several other employees. Heavier crushers have been recommended for the Ohio Copper Co.'s mill at Lark, by the general manager, George F. Waddell. The plant is treating 210 tons of ore per day at present.

UTAH COUNTY

At the mouth of the Santaquin King adit there is about 200 tons of \$8 to \$10 ore containing lead and silver, while 200 tons of \$30 ore is ready for shipping. An ore-shoot containing 38 to 40% zinc was recently opened, and further driving cut silver-lead ore. This is in limestone. Further development in the mine gives assays of 8 oz. silver, 51% lead, and 9.2% iron. The adit, 4½ by 6½ ft. in the clear, is to be extended 100 ft., at a cost of \$6.50 per foot. Transport facilities have hindered profitable work in the past, but on January 12 a contract was let to the Utah Industrial Transportation Co. to install, at its own expense, a monorail system of tramway to carry ore to the railway. This will cost about \$35,000.

WAYNE COUNTY

A good discovery of carnotite (uranium ore) has been made 2½ miles southeast of Fonita by S. W. Mulberry, an old prospector. Two tons of the ore was taken to Richfield. The deposit is irregular in size, and occurs between white and red sandstone. There is also a 75-ft. layer of blue clay. Eleven claims has been staked, and 11 outfits are going to the new field.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The following ore production was made from mines at Republic during November and December:

| | November, | December, |
|-----------------------------|-----------|-----------|
| | tons. | tons. |
| Ben Hur | 3,080 | 3,322 |
| Knob Hill | 310 | 2,002 |
| Hope company | 71 | |
| Quilp | 92 | 235 |
| Republic Mines Corporation: | | |
| Lone Pine | 227 | |
| Pearl | 80 | |
| Surprise | 2,180 | 1,709 |
| Total | 6,046 | 7,268 |

The output for December exceeded that of any month of 1913. The January yield will not be as large as the two previous terms.

Republic, January 25.

CANADA

BRITISH COLUMBIA

The sixteenth annual convention of District 6, Western Federation of Miners, was held at Nelson on January 20, when there were delegates from all mining camps in the Kootenai and Boundary districts. James Cuthbertson of Greenwood is president. He spoke on compensation in Washington, and a universal 8-hour day. The membership of the union increased 20% in 1913.

ONTARIO

The Miller Lake-O'Brien company, at Gowganda, is producing 60,000 oz. silver per month. The Mann mine is being sunk to 200 ft., and a car of rich ore is to be shipped.

Two Italians were sentenced to six months imprisonment on January 20 for stealing silver ore from Cobalt. The ore was returned to the Mine Owners' Association. During the work of draining Cobalt lake, the foreman, W. E. Janes, was killed by a falling derrick. In December, the McKinley-Darragh-Savage property produced 159,022 oz. silver, making the year's total 2,212,557 oz. This is a decrease of about 500,000 oz. compared with 1912. The large tube-mill at the plant was out of commission in December. On February 14 the Seneca-Superior Mining Co. will pay a dividend of 12½%, equal to \$59,548. The total paid since February 15, 1913, will be \$369,297.

YUKON

A dredging record was put up during the past season by No. 2 boat of the Canadian Klondyke Co., which operated 271 days, or 33 days longer than the previous record, which was held by the same boat.

KOREA

The Oriental Consolidated Mining Co. reports as follows for November: 240 stamps crushed 25,602 tons of ore yielding \$134,633 from all departments. Operating costs were \$97,281, leaving a profit of \$37,352, of which \$11,761 was spent on improvements and development. The net profit was therefore \$25,591.

JAPAN

The output of the Imperial Steel Works at Wakamatsu for 1913 is placed at 200,000 tons of pig iron and the profit for the year is estimated at \$2,000,000. This includes profit on final products, a large variety of which are made at the works.

MEXICO

CHIHUAHUA

The Batopilas Mining Co. reports as follows for the year ended December 31, 1912: total revenue, P742,568; expenditure, interest, etc., P582,473; prog't, P160,095. There is a surplus of \$194,913, an increase over the previous year. Cash totals \$58,027; current liabilities, \$46,260; and current assets, \$174,372.

SONORA

The Lucky Tiger-Combination company of Kansas City, Missouri, reports as follows for December:

| | |
|--|-----------|
| Ore crushed, tons | 6,209 |
| Tailing treated, tons | 7,672 |
| Revenue from shipping ore, concentrate, and bullion .. | \$148,092 |
| Expenditure, including development, marketing, and taxes | 89,041 |
| Profit | \$ 59,051 |

A dividend, No. 53, of 6c. per share was paid on January 20. On December 18 and January 8 all outstanding bonds were authorized to be purchased, this to take place on January 26 and February 1.

Schools and Societies

The INSTITUTION OF MINING AND METALLURGY, on January 13, celebrated its twenty-second anniversary, and the opening of its new quarters at 1 Finsbury Circus, London, E. C.

The Mine Owners and Operators' Association of the Cripple Creek district met at Colorado Springs on January 25. The meeting was called to order by the president, E. A. Colburn. Mine taxation was one of the subjects discussed.

Colorado mining men will hold a convention on February 19, at a place to be decided later. There will be present representatives of the counties, Bureau of Mines, U. S. Geological Survey, state geologists, and the commissioner of mines, T. R. Henahan.

The UNIVERSITY OF ARIZONA will give a six weeks' course in mining early in the spring. Twelve distinct branches of the industry will be included, from mineralogy to ore treatment. The mining department of the university has collected information regarding the working of 1397 mines in the state.

The INSTITUTION OF PETROLEUM TECHNOLOGISTS in London has appointed its first council. The president is Sir Boverton Redwood, with Lord Cowdray of Midhurst as vice-president, and 15 ordinary members. David T. Day, of the U. S. Geological Survey, and C. Engler have been elected honorary members. Over 100 applications have been received for membership.

The third annual mining exhibition, under the auspices of the CHEMICAL, METALLURGICAL, AND MINING SOCIETY OF SOUTH AFRICA, will be held at Johannesburg, from May 19 to 29, 1914. Commercial firms, for whom a limited space will be provided, desirous of exhibiting machinery, apparatus, natural products, etc., will be charged for the space occupied at from \$1.25 to \$2.50 per square foot, according to position, and whether stands are provided or not.

The Montana branch of the AMERICAN INSTITUTE OF MINING ENGINEERS will hold its annual meeting at Butte on February 6. This includes a dinner, business meeting, and reading the following papers: 'The Drumlunnon Mine,' by C. W. Goodale; 'Reverberatory Smelting with Low-Grade Coal,' by C. E. Demond; and 'The Labor Crisis in Chile,' by Bancroft Gore. E. P. Mathewson is chairman, and D. C. Bard secretary.

The UNIVERSITY OF ILLINOIS has issued an interesting illustrated booklet covering the work of the College of Engineering. This includes 11 departments covering architecture, civil, electrical, mechanical, mining, municipal, sanitary, and railway engineering, mechanics and physics, and the experiment station. A short course in highway engineering will be given from January 19 to 31, 1914. There are no charges for the course, and it is open to anybody without examination. This is an important subject and a series of highly interesting practical demonstrations is to be shown.

The SAFETY FIRST CONVENTION opened at Reno on January 26. The following papers were presented on the first day: 'The Safety-First Movement in Nevada,' by John J. Mullin; 'Safety First on the Oregon Short Line,' by L. E. Abbott; 'Safety First in Practice,' by Frank Ingram; 'Safety Regulations for Electrical Power Companies,' by W. K. Freudenberger (this was discussed by officials of the principal power concerns of Nevada); and 'Electric Headlights,' by J. G. Scrugham, which was discussed by representatives of engineers, firemen, trainmen, and conductors of railroads in Nevada. The evening session consisted of demonstrations of electricity by members of the University of Nevada, and motion pictures on various subjects.

Personal

L. A. GREENE is in New York.

W. H. LANAGAN is in London.

T. W. E. DAVID is in London.

F. LYNWOOD GARRISON is in Colorado.

R. Y. HANLON is at Santa Ynez, California.

E. H. LESLIE is visiting Arizona mining regions.

J. FORDYCE BALFOUR has returned to Nigeria from London.

J. E. SPURR is inspecting the Tonopah Mining Co.'s properties.

PAUL M. PAINE has moved from Fellows to Taft, California.

F. A. VOORHEES left San Francisco, and is at Pearce, Arizona.

R. E. CRANSTON and R. H. ELLIOTT are sampling the Zeila mine at Jackson.

J. N. ESSELSTYN has moved from Orogrande, New Mexico, to Denver, Colorado.

G. MACFARLANE, manager at the Wallis property in West Africa, is in London.

REIJI KANDA has been investigating operating conditions at the Hasami gold mine.

T. N. TURNER, who has been with the Orsk Goldfields in Siberia, has returned to Palo Alto.

JOHN MOCINE will become manager for the National Copper M. Co., at Mullan, succeeding CHARLES MCKINNIS.

ALBERT BURCH has been elected president and ELMER KING vice president of the newly organized Goldfield Unity Club.

PEECY E. BARBOUR has returned to North Carolina from attending the annual meeting of the Mining and Metallurgical Society in New York.

Obituary

GODFREY D. DOVETON, the well known and active metallurgist, died at Guadalajara January 20 as the result of an injury sustained the day before. While working around machinery his right arm was caught in gearing and he was so badly injured that he did not recover. Doveton was a New Zealander, one of the pupils of James Park. He studied at Auckland University College, 1891-93, and the next two years at the famous School of Mines on the Thames where so much of the pioneer work on the cyanide process originated. After graduation he worked for five years with various New Zealand companies, including the Waionio, Puhī Puhī, Anglo Continental, and the Moanatairi. In 1900 he came to America, making his headquarters at Denver. Almost immediately he was called to take charge of the mill at the Camp Bird mine, and he spent two years there as superintendent and metallurgist. In 1902-04 he served as metallurgical engineer for the Creston-Colorado, returning to the United States to take up general consulting work, in which he was associated with Spurr and Cox. He did especially important work at Cripple Creek and Tonopah, being responsible for the designing of some of the largest mills in Nevada. In 1905-06 he was with the Lincoln California at Telluride, Colorado, and since then has been almost continuously in Mexico, where he has done notable work at El Oro, Zacatecas, and Pachuca especially. When the Sta. Gertrudis mill was to be built Doveton was selected to make the preliminary studies and to determine the process and plant to be adopted. His report was a model of careful conscientious work. That, however, was characteristic of his entire career and he obtained an enviable reputation for fairness and thoroughness in all that he did. His death is a real loss to the industry and his career illustrates the fact that hard work and ability carry men far in the profession of metallurgy.

The Metal Markets

LOCAL METAL PRICES

San Francisco, January 29.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, January 28.—There has been a steady increase in the price of copper during the past week, the market is active and firm, with good demand from Europe. American smelting agencies and Hirsch are quoting 14 1/4 c. for electrolytic, and the Amalgamated 14 1/4 c., in London. There is a fair inquiry, and Continental dealers are selling at 14 1/2 c. per pound. The Greene Cananea Copper Co. paid a dividend of 50c. per share today. Earnings are at the rate of \$6 per share per annum. Ray Consolidated copper output for December was 5,232,167 lb., and Utah Copper, 10,624,790 lb. Lead is firm, and spelter is strong. London metal prices yesterday were: copper, £65 12s.6d. and £65 17s.6d.; lead £20; spelter, £21 10s.; and tin, £179 5s. for spot, up £1 10s., and £180 for futures, up £1 10s., with strong demand. Investment issues were buoyant and Consols advanced 1/4. Bonds were active in New York, and shares sold on the Stock Exchange on January 28 totaled 460,598.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | Average week ending. |

| June | 61.29 | 59.03 | Dec. | 63.38 | 57.73 |

Writing on January 8, Pixley and Abell state that from January 2 to 5 the market remained quiet and somewhat dull in tone, as the demand was barely sufficient to absorb the daily offerings. On the 6th, a premium of 1/16d. (1/32c.) was established on cash, the effect of which was immediately felt, for, on the following day, the Indian bazaars, doubtless having fears of another 'corner,' sent large covering orders for near dates, and in addition limited orders for shipment, in consequence of which the premium increased 1/4d. (1/8c.), the quotations being 26 3/4d. (53 1/2c.) and 26 7/16d. (53 3/4c.), respectively. Today the premium has eased off to 1/8d. (1/16c.), as the buying has been chiefly for forward dates, and, at about the previous day's difference, there were 'bulls' who were willing to extend their purchases falling due shortly for a further two months. There are still a good many 'bears' whose sales must be covered during this month, and their position may not be an easy one to adjust, as the Continent is shipping freely from London, while silver worth £150,000 was sent to Bombay.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

| Date. | Average week ending |

| June | 17.23 | 14.71 | Dec. | 17.37 | 14.25 |

The copper market gained strength during last week. On January 19 one of the large agencies sold 18,000,000 lb. at a little under 14 1/4 c. (this includes delivery charges and 30 days interest). The following day less business was done, but the price was firm at 14 1/4 c. On January 23 the United Metals Selling (Amalgamated) asked 14 1/4 c., and London quotations advanced 5s. to £67 5s. The following day a fair business was done at this price. Exports of copper for the week ended January 22 totaled 8822 tons; since January 1, 25,217 tons, and 17,967 tons in the same period last year.

Preliminary estimates by L. Vogelstein & Co., of the 1913 copper production in the world give a total of 989,000 tons, as against 1,006,900 tons in 1912. Principal decreases were in the United States and Mexico. The world's consumption was 1,043,500 tons. Stocks in Europe at the end of the past four years were as follows: 94,800, 60,750, 35,041, and 23,670 tons, respectively. Prices moved illogically compared with statistics, for while stocks decreased, prices have fallen. Inasmuch as there is no immediate prospect of increased smelter production or imports, it is reasonable to assume that refinery output must decrease during the first half of 1914.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Jan. 15..... | 39.50 |
|--------------|--------------|-------|
| Dec. 31..... | 40.00 | |
| Jan. 8..... | 39.50 | 39.00 |

| Monthly averages. | 1912. | 1913. |
|-------------------|-------|-------|
| Jan. | 43.75 | 39.37 |
| Feb. | 46.00 | 41.00 |
| Mch. | 46.00 | 40.20 |
| Apr. | 42.25 | 41.00 |
| May | 41.75 | 40.25 |
| June | 41.30 | 41.00 |

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

| Date. | Average week ending |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

| | 1912. | 1913. | | 1912. | 1913. |

Portland Cement Production

According to returns received by the U. S. Geological Survey up to January 12, 1914, it is estimated by Ernest F. Burdard that the quantity of portland cement manufactured in the United States in 1913 was approximately 92,406,000 bbl., compared with 82,438,096 bbl. in 1912, an increase of about 9,967,900 bbl., or 12%. The estimated shipments of portland cement during 1913 were 88,853,000 bbl., compared with 85,012,555 bbl. in 1912, an increase of about 3,840,400 bbl., or 4.5%. On account of a large surplus of production over shipments, stocks of cement at the mills apparently increased more than 45%, or from 7,811,329 bbl. in 1912 to 11,375,000 bbl. at the close of 1913. In 1913 the relations between production and shipments were the reverse of those for 1912, when shipments exceeded production. It may be necessary to revise considerably the estimates of stocks, but it is believed that these figures for production and shipments are very close to those that will be shown by complete returns from all producers. The average price per barrel was appreciably higher than in 1912, several plants in the Central and Eastern states reporting increases of 10 to 25 c., while there were small decreases in the Rocky Mountain district.

Gas, Tar, and Ammonia Production

Artificial gas produced in the United States in 1912, as reported by 1062 establishments, amounted to 228,076,510,000 cu. ft. About 7% was lost or unaccounted for, so that the quantity sold or utilized was 212,391,168,000 cu. ft. This was valued at \$148,282,725, or 70c. per 1000 cu. ft. Coal gas used for illumination was 31,864,052,000, and for fuel purposes 57,829,320,000 cu. ft. Oil and water gas used for illumination was 68,136,269,000 and for fuel 54,561,527,000 cu. ft. The products in manufacturing gas from coal were 12,490,757 short tons of coke, valued at \$48,380,009; 134,796,438 gal. of tar, valued at \$3,802,047; 51,527,074 lb. of anhydrous ammonia (the ammonia liquor being reduced, when strength of liquor was reported, to its equivalent in NH₃), valued at \$4,776,386; 35,242,549 gal. of ammonia liquor (strength not reported), valued at \$1,002,807; and 99,070,777 lb. of ammonium sulphate, valued at \$3,740,075, according to Edward W. Parker, of the U. S. Geological Survey. The output of tar was 134,796,438 gal., worth \$3,802,047, and that from oil and water-gas plants was 9,168,834 gal., worth \$229,582.

SULPHURIC ACID manufactured by the Tennessee Copper Co. in December amounted to 20,100 tons, and totaled 197,673 tons during the past year.

Recent Patents

1,071,893.—PROCESS OF REMOVING SUSPENDED MATTER FROM GASEOUS FLUIDS. Henry L. Doherty, N. Y.

The process of separating from a body of gaseous fluid particles suspended therein, which consists in imparting a spiral motion to the said gaseous fluid first in one direction of rotation and then in the opposite direction.

1,072,010.—PROCESS OF PRODUCING ALKALI-METAL HYDROXIDES DIRECTLY FROM ALKALI-METAL CHLORIDES. Julius Kersten, Dellbrück, near Cologne, Germany.

Mixing an aqueous solution of an alkali metal chloride with hydroxide of lead, whereby an alkali metal hydroxide containing basic chloride of lead is obtained, and in separating the chloride of lead from the alkali metal hydroxide.

1,071,856.—TREATMENT OF METAL-BEARING SOLUTIONS. Edgar Arthur Ashcroft, Balestrand, Norway.

Process for the treatment of metal-bearing solutions to obtain the zinc therefrom which consists in adding to the solution a cyanogen compound and subsequently heating the mixture, whereby the zinc is obtained in the form of an insoluble compound.

1,071,962.—AUTOMATIC CHARGING DEVICE FOR ROASTING-FURNACES AND THE LIKE. Ludwig Singer, Bochum, Germany.

For roasting-furnace and the like, comprising a plurality of bottomless exchangeable charging-vessels and a rotatable false bottom provided with a discharge-opening adapted to register successively with the lower end of each of said charging vessels.

1,071,917.—DEWATERING DEVICE OR MEANS FOR SEPARATING SOLIDS AND LIQUIDS. Wilbur Alson Hendryx, New York, N. Y.

A tank having a lower converging portion, an upwardly extending undivided conduit directly connected to the bottom of said lower portion and a pair of oppositely rotating screws in such conduit, said screws having their edges approaching each other and the sides of the conduit.

1,072,209.—PROCESS OF EXTRACTING ZINC FROM RESIDUES CONTAINING ZINC, ESPECIALLY SLAGS, IN REVERBERATORY FURNACES. Adolphe Henri Desgraz, Hanover, Germany.

Recovering easily reducible and volatile metal from substances containing the same, which consists in forming such substances to a molten liquid bath of slag, and reacting upon said molten bath with a suitable basic agent, thereby driving off said metal from the bath.

1,072,276.—MAGNETIC SEPARATOR. Georg Ullrich, Magdeburg, Germany.

A stationary magnet, a non-magnetic guard entirely covering the active part of said magnet and against which guard the material is held by the magnet, said guard rotating to remove the adhering material when beyond the action of said magnet, a counterpole adjacent to said magnet also attracting the material, said counterpole also constructed to rotate.

1,071,975.—ORE CONCENTRATOR. Joseph Weatherby, New Cumberland, Pa., assignor by mesne assignments to Electric Ore Separator Co., New Cumberland, Pa., a corporation of Delaware.

Combination with a table, of means for feeding materials to be separated to said table, means for agitating said table to pass said materials gradually along the table to effect stratification and separation thereof, and means for creating a magnetic field in the path of the moving material and with the lines of force converging to lines lying in a plane coincident with the path of the body of material traveling over the table.

1,071,850.—ORE CONCENTRATOR. Henry Ellsworth Wood, Denver, Colo.

The combination with an inclined vibrating ore concentrating table of the kind described and provided with longitudinal riffles, of means for maintaining a stream of water transversely across the same at the feed end, means for feeding the material to be treated in a finely divided state upon the surface of the stream, a spillway adjacent the feed end of the table to permit the discharge from the table of the surface film of said stream with the particles floating thereon, and means for separately discharging the submerged concentrates and gangue from the table as set forth.

1,072,359.—ROCK DRILL WITH WATER FEED. Alexander Palmros, Syracuse, N. Y., assignor to The Pneumatic Electric Co., Syracuse, N. Y., a corporation of New York.

In a rock drill and a housing therefor, the combination with a reciprocating hammer in the housing, a drill steel and a chuck for said steel, of a dolly pin situated between the hammer and the drill steel, a duct in the drill steel and a corresponding duct in the dolly pin, an elastic bulb inclosing part of the dolly pin, a hollow chamber in said bulb communicating with the duct in said dolly pin and connection for supplying water under pressure to said chamber.

1,072,277.—APPARATUS FOR THE MAGNETIC SEPARATION OF ORES AND OTHER MATERIAL. Georg Ullrich, Magdeburg, Germany.

Means for producing a plurality of magnetic fields in a circle about a vertical axis, in each magnetic field two stationary poles of which the upper pole comprises lamellae adjustable vertically and independently of each other, said lamellae being downwardly sharpened, for the purpose of providing, in each magnetic field, a plurality of single adjustable zones and an extracting body revolving between said poles, said extracting body being corrugated to conform in shape with the sharpened part of said lamellae and means for conveying the material to be separated between the upper and the lower poles.

1,072,362.—SAFETY CLUTCH FOR MINE CAGES. Brereton Burgess Roberts, Cymla, Neath, Wales.

An automatic safety device for mine-cages, lifts, and the like, comprising guide ropes, a movable plate, a pair of jaws mounted at each end thereof, and adapted to grip the guide ropes, slidable collars adapted to cause said jaws to grip said guide ropes, a spring adapted to impel said sliding collars, said spring being normally restrained by tension of the winding rope, a connection between said movable plate and the cage consisting of a rod projecting upward from the cage, and passing loosely through the said plate, a block through which said rod also passes, and rods connecting said block with the aforesaid collars, said rod having a shoulder at its upper end to retain said block.

1,071,891.—GOLD-SAVING MACHINE. Loyd C. Dibert, San Francisco, Cal.

The combination of a horizontally disposed screen shoe inclining in the direction of its length and having a discharge chute extending from end to end with an outlet substantially midway of the ends of the shoe and to the side thereof, a gold-saving table extending transversely relative to the shoe and of a width greater than the discharge outlet of the shoe and less than the length of the latter, the head of the table being directly beneath the discharge outlet and the table inclining from this point downwardly, yieldable supports for the shoe and the table, a rotatable shaft arranged at a point substantially between the shoe and table and extending transversely relative to the shoe, pitman rods, one for the shoe and the table each, having eccentric connections with said shaft and adapted to simultaneously impart shaking movements to the shoe and table in relative transverse directions about their yieldable supports.

Book Reviews

ECONOMIC GEOLOGY. By Charles H. Richardson. Pp. 320. Ill., index. McGraw-Hill Book Co., 1913. For sale by the *Mining and Scientific Press*. Price \$2.50.

This book makes an excellent first impression, being well printed and illustrated with fresh, up-to-date pictures. Unfortunately, this favorable impression is not strengthened by a study of the text. The latter does not show that intimate first-hand knowledge of the subject which alone permits wise choice from the bulk of material on ore deposits now available, and the English is so poor that it is charitable to assume that in places the reverse of what is stated was what the author intended to say. For example, the statement is made (p. 3): "If ore deposits are found in the sedimentary rocks as they sometimes are (with the exception of the lead and zinc deposits of Missouri), the minerals were associated with great rock masses whose detritus furnished the material for the new geological formation." In fact, of course, the lead and zinc deposits of Missouri are preëminent among deposits found in sedimentary rocks. The illustrations, while attractive, are used with little discrimination. For example (p. 112), a figure (71) typical of the 'flats and pitches' of Wisconsin, is used as follows: "In Missouri, galenite occurs filling large cavities as chamber deposits and as gash veins; also it occurs in what is known as flats and pitches." In fact, both gash veins and 'flats and pitches' are typical of Wisconsin. The latter do not occur in Missouri with the possible exception of some rare and far from typical instances. The discussion of zinc smelting is entirely out of focus. The 'calcination process' which is discussed first (p. 265) and at more length than distillation, is of no present large commercial importance. The gain of the Kansas zinc smelters over those at La Salle, Peru, and other points where "Joplin ores were formerly treated" (p. 267) has long since been reversed; the common method of making zinc oxide is not "by burning metallic zinc," but by treatment of ore; and in other details the discussion gives a false impression. The whole book is 'off centre.' It is a pity so much good effort should have gone to waste.

RUSSIAN MINING REGULATIONS. By J. Harper. P. 144. *The Mining Magazine*, London. For sale by the *Mining and Scientific Press*. Price \$2.

The difficulties attendant upon mining operations in Russia have been said to be principally those due to politic, racial, and economic conditions, and the mining law is by no means a small obstacle in the path of the uninitiated foreigner beginning operations on Russian soil; he being constantly told that he cannot do this or that thing according to his own designs as it is contrary to the government regulations. It is therefore important that every mining engineer contemplating going to Russia be conversant with the mining laws of that country and that every company operating in Russia should supply their managers with a copy of the laws governing mining. A knowledge of the law is a protection to the engineer, in that it stands between him and almost any eventuality that is likely to arise in the conduct of mining operations. In special cases not provided for in the regulations, it is usually possible to get permission to proceed by simply furnishing the authorities with plans and descriptions of the proposed undertaking. This has been found necessary in the sinking of inclined shafts, which are not provided for in the regulations, the use of locked coil hoisting ropes and other instances. In that this edition is the only English translation of the general regulations pertaining to metal mining, every engineer interested in Russian mines should include in his library a copy.

The Chicago Portable Mine Hoist

Portable mine hoists are one of the recent improvements that are decreasing costs and lightening the work and worries of underground managers. The Chicago Pneumatic Tool Co. has perfected a hoist of this type that has a number of novel features sure to commend it. The weight is 300 lb., so that the hoist may be handled as easily as a drill. It may be mounted or dismounted in a few minutes and is so small as to be easily stowed out of the way. It may be mounted on a column bar or set as a stationary hoist. It is described by the makers as below.

The Chicago portable mine hoist operates by a reversible two-cylinder pneumatic motor through a chain of gears cut out from solid steel and hardened. This gearing is so designed that a brake is unnecessary. It instantly and positively locks, whether in raising or lowering the load, the moment the motor stops, and it is impossible for the load to slip even though the air is cut off for a whole day. The hoist will coil 200 ft. of $\frac{5}{16}$ -in. wire rope and hoist 650 lb. at a rope speed of 90 ft. per minute. This it is guaranteed to do with 80 lb. air-pressure, but as a matter of fact is tested with much heavier loads. The hoist is so designed that the rope cannot possibly run off the drum. The gears are incased in a closed gear box, which not only protects the teeth, but also insures the careless operator against personal injury and permits of automatic lubrication. The motor consists of two double-acting oscillating cylinders set at right angles in a closed case. There is no movable valve mechanism, as the oscillation of the cylinders opens and closes the ports. A quantity of oil is kept in the case, so that the crank in revolving lubricates itself and dashes the oil on the cylinder seats, from which the air carries it through the inlet ports in sufficient quantities to thoroughly lubricate the pistons. The air is controlled by a slide valve, which closes when in the central position and starts or reverses the motor as it may be thrown to the right or left. The valve is thrown by a lever. When this lever is released by the operator the valve is self-closing. This automatic action of the valve positively eliminates all danger of the hoist creeping and doing damage due to a slight displacement of the valve, since it is necessary to hold the valve open in order to admit any air to the cylinder. The cylinders are bored true, and automatically adjustable to their valve-seats, the adjustment being simple and made from the outside of the motor case. The piston rods are ground. The stuffing boxes are ample and contain sufficient packing for long wear. All bearings are bronze bushed.

The Younger Generation of Rock-Drills

*One of the most useful additions to the rock-drill family in recent years is the perfected hand hammer-drill, known in various mining districts by different terms of endearment such as 'Plugger' drill, 'Jap' drill, or 'Jackhammer.' This general type of drill is now extensively employed for such purposes as sinking shafts, digging trenches, in road work, trimming tunnels, breaking up boulders, quarry work, stripping coal land, picking coal bands, tearing up pavements, foundation work, 'glory-hole' mining, and similar operations.

The hand hammer-drill is essentially a one-man machine, its weight being 20 to 50 lb., and this has brought the type into general popularity. This is aside from the fact that the hand hammer-drill may be used in restricted quarters and more drills may be employed per unit of space, due to the absence of mounting and the elimination of helpers. The adoption of such unmounted drills has been accomplished without any sacrifice of speed. On the contrary, they have proved a material aid in securing results greater than could

*Furnished by Charles A. Hershberg of the Ingersoll-Rand Company.

be obtained with other types, and this is leaving out of consideration certain other advantages inherent in the hand type. It must be kept in mind, however, that this article applies only to work for which the hand hammer type is adapted. There are certain limitations to the possibilities of the type which will be referred to later.

The time factor in drilling may be considered as made

AUTOMATICALLY ROTATED HAND DRILL.

up of the following elements: Setting up the drill; drilling the hole; shifting position; removal.

The hand hammer-drill is used without mounting. Hence the time for setting up is eliminated. The time consumed in drilling the hole may be said to depend upon the size of the hole to be drilled, the method of applying the power to the bit, the facility with which steels may be changed, and the manner in which the drill-hole is kept clean of cuttings. With the types of mounted drills in which steel reciprocates with a piston, it is necessary to employ steels of large diameter, with correspondingly large bits, owing to the heavy crushing done by every blow and the severe shocks to which the steel is subjected. Moreover, a certain amount of power is consumed in the rubbing of the bit against the walls of the hole, which results in very rapid wear of the bit unless sufficient metal is provided.

In contrast to this, the hand hammer-drill under discussion employs the hammer principle for delivering the blow. The steel is not reciprocated with the piston, but rests loosely in the chuck and is struck a great many light blows by a

rapidly moving piston; the bit end of the steel being at all times against the rock. It will be evident that the lateral movement of the steel is very slight (the rebound only) as compared to the reciprocating of several inches with the mounted type. With the hand type, the great reduction in rubbing of the bit against the walls of the hole reduces the wear on the wings of the bit, so that bits of smaller gauge variations may be employed. In other words, to obtain a given size of hole at the bottom, a smaller size of starter bit may be employed than would be advisable with the mounted type of drill. In the one type the steel is rigidly clamped to the piston rod; in the other it rests loosely in the chuck and is prevented from going too far into the cylinder by a collar on the shank of the steel or by means of an anvil-block interposed between the end of the steel and the piston. The latter constructions mean less time consumed while changing steels and in removing steels so as to clean the hole. Of course, with types of drills having automatic hole-cleaning features the time consumed in cleaning the hole may be practically eliminated from consideration. The time required for removing the steel from the hole is still further reduced when a steel holder is employed, especially if it is of a type that can be slipped into place quickly.

In the mounted type the steel is invariably automatically rotated. In the hand type there are two methods of rotation, by hand and automatically. The drill runner must constantly rotate the drill back and forth through an angle of about 45° or the hole will become rifled, with consequent sticking of the steel and delay in removing it. A drill embodying automatic rotation will produce a more uniform hole and will relieve the operator of the most irksome part of his work, thus permitting him to work faster and with little or no necessity for periods of rest.

The time required for mounting and for the various operations of shifting mounted types of drills is often greater than the actual time of cutting, whereas with the hand hammer drill this element is practically eliminated, it requiring but a few seconds to shift. When it comes to removing the equipment preparatory to blasting, the absence of mounting, aside from the great disparity in weight (about 250 lb. as against 40 lb.) is an important item in favor of the newer type of drill.

Of course, this type of drill has its limitations, principal among which is the depth of hole that may be drilled economically. This varies, depending solely upon the nature of the ground to be drilled. In extremely hard rock the drilling range has been as low as 5 or 6 ft., in medium ground around 12 ft., and in favorable ground about 20 feet.

EDITORIAL

THE more careful methods of mining in foreign countries, as well as the stricter regulations and supervision, result in much lower fatality rates abroad than in the United States. The statistics for the year 1911 show that the fatality rates in Australasia varied from 0.68 to 2.33 per thousand. In Great Britain the rate was 1.48; in Japan, 1.76; and in Spain, 1.49 per thousand. In the Transvaal the high fatality rate (4.14) is probably accounted for by the enormous number of native laborers employed in the mines.

COLUMBIA UNIVERSITY students, according to the report of the director of the University employment office, earned \$56,705 during their summer vacation. The vocations of the 460 students who worked during the summer were both numerous and varied, including all the arts and trades from boot-black, plasterer, caddie, and baker, to fakir at the country fairs. With such a variety of talent being yearly moulded into doctors, lawyers, and engineers, we can but realize what an important position our great universities hold in the shaping of the youthful mind and giving direction to its efforts.

IS Wall Street the barometer of business conditions in the United States? No doubt this is generally thought to be the case, yet we venture to question it. One of our contributors has succinctly remarked that "the eastern investor is a speculator in stocks and not a buyer of mining claims." According to newspaper headlines we are informed that Wall Street was hard hit by the poor trade in 1913, and that the past year was almost a calamitous one in business circles generally. Yet on another page of the same paper we read that the year's exports were the largest in the history of the United States, and that the balance of trade in favor of this country exceeded the records of any previous year. Incidentally we note that the importation of diamonds and other gems broke all records, the value being about \$46,000,000, or more than half that of the total gold production of the country. The recent depression in Wall Street seems to be less indicative of poor business conditions than of a tendency on the part of the public to cease speculating, both in Wall Street and in mining claims, and to use their money for personal adornment.

Discovery Versus a Permit System

Discovery, as the proper basis for title to mineral lands, is discussed in detail and with great clearness in this issue by Mr. W. E. Colby, whose knowledge of the facts and the law in the case, as well as his disposition to be constructive rather than merely a 'standpatter,' lends great weight to what he says. Probably few have realized how ancient and how widely recognized the right of discovery is, and it is true, as is urged, that a rule found good for so many years and by so many different peoples, must have merit. It is also true that in legal matters it is wise to build on to an existing system rather than to be too ready to start with a clean slate. All this may be admitted without materially weakening the position of those who urge that the time has come for radical changes. We are confronted by certain stubborn facts, and out of them demand for revision has arisen.

In the first place, there are the withdrawn lands. Initially only coal lands were withheld from entry "pending classification." Later oil land, phosphate lands, potash lands, were added to the category, and now—and we understand that of this Mr. Colby approves—even presumed copper-bearing lands have been withdrawn in certain areas where there are no surface showings of the orebodies assumed to be present at depth. Furthermore, it seems entirely probable that there will be more classes of lands withdrawn in the future than the reverse. In the second place, the public domain is passing under private ownership with great rapidity. Figures need not be quoted, as the fact is one patent to all who live in the Western states. The bulk of the land is being acquired as non-mineral land, even in regions where there would seem to be a good presumption of mineral. Unless some measure be enacted and some step taken, there will soon be little land left for "free exploration and discovery." Finally, it is generally admitted by those who have watched the search for ores that the opportunities for making discoveries of ore-shoots at the surface, by the simple methods of prospecting hitherto in vogue, are becoming extremely rare. To find additional orebodies, we must, in general, adopt newer and more expensive methods of exploration. These require longer time, and as they involve more expense they warrant granting larger areas to the one undertaking the venture. Also, they warrant giving such explorer, during the period prior to discovery, more than a shadowy and constructive right to undisturbed possession of the ground that he is trying to prove to be mineral in character. In fact, under the present law such an explorer is put to needless anxiety and useless expense. Take as a case a secondary copper deposit similar to that at Miami. What good purpose is served by covering such ground with 'quartz locations'—each with a theoretical extralateral right—and either requiring or allowing the proverbial \$100 worth of work per claim during a tentative period;

especially if this work take the form of 10-foot pits in a capping 200 feet thick?

For the case of the rare 'true fissure lode,' with a shoot outcropping at the surface, the old system was excellent; but for the search for mineral in the western part of the United States as it is conducted in 1914 and must be from now on, these simple laws of our forefathers are clumsy, crude, and unnecessarily vexatious and expensive. Discovery may properly be made a condition to the giving of final title; but a form of temporary permit, coupled with withdrawal of any presumably non-mineral land from any other form of entry, or the reservation of mineral rights in all lands taken under non-mineral title in certain defined areas, may be added to the present system, we believe, with great benefit to the industry.

Gold Placers of the Marañon

New York and eastern investors are being asked to subscribe for the shares of Peru Gold Placers, Incorporated, a company formed to work certain ancient placers on the Marañon river in eastern Peru. The Company is well officered and the directorate includes Messrs. Alexis I. Du Pont and John J. Raskob of the Du Pont de Nemours Powder company; Henry H. Bowman of the Springfield National Bank; David T. Marvel, former judge of the Delaware Supreme Court; Charles S. Miller and O. R. Hartman of the Ascot Tobacco Works; and William B. Bassett of Bassett & Company, New York. It is capitalized at \$20,000,000 in \$5 shares. Of the total, 1,200,000 shares have been set aside for the benefit of the treasury and 150,000 are now being offered at \$2 per share. Subscriptions are said to have come in rapidly and it was at one time announced that the entire allotment had been taken. We understand that this was premature but that the issue has been underwritten by responsible men. The concern is being floated upon public faith in the directors and an engineer's report made by Mr. Raymond McCune. The placers are in the territory east of the Andes in which gold undoubtedly occurs and from which stories of enormous wealth to be won by mining have been coming for years. Our readers will recall the articles by Mr. Pierre Bourey and by Messrs. C. S. Haley and C. A. Rodegerdts that we have printed within the year. These gave definite conceptions of the character of the country and of the difficulties to be faced in mining or prospecting. These general impressions warrant an extremely critical attitude toward any project that appeals to the public for funds and that is capitalized at \$20,000,000. This disposition to scrutinize the matter closely is all the more warranted in the face of claims that gravel to the value of \$106,106,482 has been found as a result of one season's work in sinking test pits. It is not the first time that the 'placers of the Incas' have been reported to have been found, nor is it the first time that stories of fabulous wealth have come from the Andes.

Mr. Raymond McCune, who is general manager for the Company and at the same time makes the report upon which stock is offered the public, is a son of Mr. A. W. McCune, at one time of Salt Lake City and well known as an able railroad builder in the countries along the West Coast of South America. Mr. Raymond McCune is not, as is stated in advertising literature circulated for the Company, a graduate of Columbia. He left the school in fact without graduating and with numerous conditions. This would by no means prevent his later becoming a good engineer. It is, however, to his discredit that advertising literature is allowed to be circulated claiming for him graduation when this is not in accord with the facts. Mr. McCune has had extensive experience in connection with his father's railroad projects and may be safely assumed to be entirely familiar with the country in which it is proposed to mine, and with the conduct of expeditions through, and business enterprises in, such a country. From that point of view his experience has been excellent. His ability to test placer ground is less certain and must be judged by the report to which he has put his name. Here, as it seems to us, the evidence is inadequate to sustain the conclusions drawn. The deposit is taken at 22,966 yards long, 317 yards wide, and 18 yards deep, and the resulting 131,150,840 cubic yards is assumed to have an average value of 80.9 cents per yard. This average value was obtained by combining the results of 185 test pits. There are several doubtful points, among which we may call attention to the fact that Mr. McCune has assumed an average depth of 18 yards. Only two of his test pits were put down to bedrock. There may or may not be a depth of 18 yards of gravel present. Another doubtful point is the method of mining that is proposed. It is obvious from the report, together with the photographs and maps, that the usual simple method of hydraulicking would be absolutely impossible of application on this property. The conditions are quite unlike those at California placers, where the gravel in high banks can be washed down into sluices by means of giants. It should be evident to anyone that this easy and inexpensive method would be quite inapplicable to the Marañon placers, where nearly all of the gravel lies below the level of the river. The question of dump room and disposal of tailing is a vital one that has not been adequately discussed in the report. We find no estimate for hydraulic elevators; and provision for a 3000-foot diversion canal only, although the total length of the claims is said to be about twenty miles. The internal evidence obtained from a careful reading of the report convinces us that the testing and sampling of these placers was not done by thoroughly experienced men, however painstaking and careful they may have been. No engineer qualified in the testing of alluvial deposits would attempt to estimate more than a hundred million cubic yards of gravel when only one or two pits had been sunk to bedrock; nor would he sink test-pits in the irregular and unsystematic manner that is described in this case. In

placers of this type it is necessary to sink series of closely spaced shafts or drill-holes to bedrock along lines drawn at right angles to the course of the river, these lines or sections being spaced at regular intervals throughout the entire length of the valley to be sampled. In this way only can accurate data be obtained concerning the distribution of the gold and the average value of the profitable gravel areas. Mr. McCune reports that he collected the black sand obtained from the samples of gravel, had this assayed, and then added the value of the gold from this source to that of the free gold obtained by panning. This practice is misleading and erroneous, inasmuch as rockers and pans will save all of the gold that can be caught in the sluices in actual practice. In addition he fails to give the depths of any of the test-pits; and gives arithmetical averages of the gold values, instead of averages correctly weighted according to the depth of the shafts and their spacing.

It is also to be remembered, with all due respect to the engineer who signs his name to this document, that this is a vendor's report; and studying the plan of capitalization it becomes evident that the 'insiders' are to have the large share of any potential profits. If all the 1,200,000 shares set aside to finance the property are needed, the insiders' share will still amount to nearly three-quarters. If, as is hoped, part of these treasury shares can be cancelled, the promoters' share will be larger. There is just one other point that may fairly be recalled in this connection. The McCune-Haggin interests were last year interested in the Ambo placers on the Huallaga river, not in the same district, and were prepared to spend considerable money upon their development when it was discovered that the samples upon which their faith was centred had been salted. We are unable to say whether Mr. Raymond McCune was a member of the syndicate that came to grief in this way or not, but the fact that responsible officers of the leading American mining company in Peru were deceived in such a matter is another reason for caution in this case. We have been among those who have faith in eventual development of important gold mines on the east side of the Andes, but repeated failures suggest that no larger expenditures be undertaken except after complete verification of the first glowing reports, and we respectfully urge the men who are serving as directors of this new enterprise to take the time necessary to check the reports that they now have before inviting the general public into such a venture.

Mr. McCune has given us an interesting and picturesque account of his journey into the jungle with a small army of retainers, and a glowing account of what he discovered. While there is no suggestion of the use of gum-drops to inspire his native workmen, we are critical enough to recall that events proved the wisdom of suspending judgment in the case of the account of the far wanderings of another eminent explorer.

Revision of the Mining Law—Discovery

By WILLIAM E. COLBY*

Much has been written of late regarding the proposed revision of the United States Mining Statutes. There seems to be a strong current running in the direction of such revision and the probabilities are that Congress will, in the near future, be urged to radically amend the existing law, if not to adopt an entirely new system.

Difficulty of Revision

It is, therefore, of the utmost importance that such action should be taken only after mature deliberation. The proposed changes and the reasons underlying such changes, should be subjected to the most searching scrutiny while the probable effect on the mining industry of the laws to be substituted in their stead should receive the most careful and critical consideration. That the general excellence of the existing law has been a material factor in the wonderful development of our mineral resources must be generally conceded. The results have abundantly justified the sagacity of the framers of the act, and for this reason, if we have outgrown the system or if some of its provisions require amendment, it would seem that the burden is on the critics to establish beyond a reasonable doubt that what they offer as a substitute will accomplish the results claimed. Unless they can practically guarantee that what they offer will materially improve existing conditions, the move will be a dangerous one and may have a disastrous effect on mining in general. Most of the criticism aimed at the existing law is of a superficial character and throws but little light on actual conditions.

Extralateral Rights and Discovery

The object of this comment is to call specific attention to some of the important details which, so far as the writer is aware, have not been satisfactorily treated by the advocates of revision. The two most radical changes proposed are the abolishment of the extralateral right and doing away with the necessity of making a discovery. Those who advocate the first change are consistent in recommending the second. If the right to follow a vein down on its dip underneath adjoining ground is denied, and vertical side boundaries are to control, then obviously discovery on claims overlying the dip of the vein and situated several hundred feet from the apex would only be possible after great expenditure of time and labor. A shaft would have to be sunk from the surface of such

outlying claims to intersect the vein in depth if the requirement of discovery on each separate claim be retained.

Is Revision Wise?

Is it wise that we should wipe out this existing discovery requirement? Let us examine the underlying reasons and anticipate if possible the consequences which must inevitably result from its abolishment. Some uninformed critics of the present law have referred to its discovery requirements as being 'an impossibility of mining law originating in America.' No one at all conversant with the origin of the discovery requirement in the mining laws of the world could possibly stand sponsor for such a statement. As Judge Lindley, in his classic work on the 'Law of Mines,' has said:

Sec. 335. DISCOVERY THE SOURCE OF THE MINER'S TITLE.—Discovery in all ages and all countries has been regarded as conferring rights or claims to reward. Gamboa, who represented the general thought of his age on this subject, was of the opinion that the discoverer of mines was even more worthy of reward than the inventor of a useful art. Hence, in the mining laws of all civilized countries the great consideration for granting mines to individuals is *discovery*.

Antiquity of Rights of Discovery

The right of a discoverer of a mine to have the preference in the concession is recognized in the mining law of nearly every country of continental Europe. In Germany in the Middle Ages, in the famous mining district of Joachimsthal, free prospectors' licenses (*Frei Schurfen*) were granted, but they gave rise to so much quarreling that they were finally abolished. Thereafter it was declared that:

"The mining regions shall be free to every miner, who shall have the right to prospect therein according to his opportunity, without the necessity of securing previous permission. Whoever, thro' the grace of God first discovers a vein shall be termed 'the first discoverer' and he shall have the first discoverer's right, viz: a *Fundgrube* (discoverer's claim). * * The Mining Director shall grant the location to no one else: * *"

Locators of claims (*maassen*) adjoining the discoverer's claim had 14 days within which to discover and expose a vein in such adjoining locations.¹ These regulations are typical of those which governed in other mining regions of Germany and Austria.

In more modern times in Germany the discovery of a vein must be followed by its regular denunciation. The actual discoverer has, for one week after his discovery, the prior claim. As in our American law,

*AUTHOR'S NOTE.—A portion of the material used in this article has been prepared for and permission to publish given by the Carnegie Institution of Research, Washington, D. C. The author is also indebted to his wife, Rachel Vrooman Colby, for valuable aid in translation of foreign authorities on mining law.

¹The foregoing information is found in 'Speculum Juris Metallici,' by Sebastian Span. It is one of the most comprehensive treatises on mining law of the early Germanic period and was published in 1698.

the discovery point must lie within the claim as laid out.²

European Practice

The French and Belgian law of mines, while not giving the discoverer an absolute preference to the concession of a mine, placed him in the list of preferred applicants. The Spanish and Mexican laws were still more liberal, for they secured to the discoverer an absolute right of property in the mine which he discovered and denounced, and no one could have any preference over him. Other persons who came after the first discoverer were entitled to take up claims "as they shall discover ore." They could not set up stakes unless they had first discovered ore. In Prussia and Sweden, he who first discovered a vein, layer, mass or bed of ore, had a right to receive the concession in preference to any third party.³ In England in the lead-mining districts of Derbyshire, where the right of free mining existed, the discoverer of a mine was entitled as a matter of right to have his claim allotted him by the Barmaster, but this could not be done "till Ore be gotten in the same ground to free it withal."⁴

It may seem strange that countries like Spain and France should have requirements in their mining codes so similar to those of Germany. Germany was the birthplace of free mining, and one would naturally expect the Roman and civil law to have had greater influence in moulding the mining institutions of these other countries bordering on the Mediterranean. This is not the fact, however. The German States had made such a success of mining, and developed the art to such a high degree, that all of the other European countries were compelled to look to it for enlightenment. In doing so they also assimilated some of the ideas of free mining which had there attained so vigorous a growth. Gamboa, in his famous 'Commentaries on the Mining Ordinances of Spain,' states that the King of Spain appointed a commission to examine the mining laws of the world with the idea of selecting those best suited to the development of the provinces in the New World, and that after exhaustive consideration, those of Germany, with their right of free mining, were found best adapted.⁵

Extensive research confirms the conclusions of the foregoing authorities. Discovery, as we are familiar with it, sprang into existence contemporaneously with the assertion of the free miner's right. This was an

³Hoover's translation of Agricola, pp. 81, 82, note; Halleck's 'De Fooz on the Law of Mines'; Deloboeque, 'Legislation des Mines'; Blavier, 'Jurisprudence des Mines'; and Gamboa, 'Ordenanzas de Minas,' are authority for the foregoing statements.

⁴'The Compleat Miner,' Hordtson, 1681; Bainbridge, 'Mines and Minerals' (5th. ed.), p. 150-151.

⁵Gamboa, 'Commentarios a las Ordenanzas de Minas' (1761), p. 6. As to the influence of German mining law on that of France, see 'Das Französische Bergrecht,' Achenbach, pp. 28-29.

early Germanic institution, similar in its origin to other examples of an exercise of free and independent personal privilege as opposed to the restraint of despotic sovereignty which have been handed down to us and become a part of our own institutions. The free miner's right involved the privilege of going out on land, usually wild and uncultivated, even though owned by some prince or royal owner (this being the equivalent of our public domain), and discovering and locating a mining claim without the express permission of such owner. This right became so general and so well established, that the royal owners were finally forced to recognize it as a valid custom, and thereby yielded up one of their prerogatives of ownership. In short, the free miner decided for himself what land he would locate, and the ostensible owner of the land had very little or nothing to say about who should be allowed to work his mineral lands. A discovery was essential in order to identify the land claimed, stamp it with mineral character, and segregate it from the great bulk of surrounding land. This free miner's right was confined to mineral land, and the burden of establishing it to be mineral devolved on the free miner, and hence the necessity of discovery which furnished his proof. It was the simplest and most practical test. This same institution of free mining, somewhat modified by circumstances, can be traced into the lead district of Derbyshire, England, and it was accompanied by the same requirement of discovery founded on the same necessities.

Origin of American Mining Law

While it is impossible to state that the so-called American mining law which sprang up in the West following the discovery of gold, was directly patterned after the Germanic or Derbyshire prototypes, it is certain that our law in its genesis owes much to the spirit and reason underlying these other systems of mining law with their free miner's right. Here in the West, in the early days, the miners exercised the same free right to go out on the public domain to discover and locate mining claims. The sovereign power did not undertake to assert its prerogative, as it might have done, by designating those who should be permitted to work its mineral lands, but it gave full sway to the choice of the individual locators and passively allowed them to make their own rules and regulations. This free miner's right, first embodied in the rules and customs of the mining districts, was later crystallized and codified into the federal statutes. For the same reasons which have existed ever since the free miner's right was first exercised, the principle of discovery was thus recognized and incorporated into the American mining law. It was necessary for the individual exercising this free right to himself stamp as mineral in character the land he sought to select, and the only feasible way in which he could do this was to make a discovery of mineral. This served a double purpose, for it furnished evidence of

good faith on his part in claiming the land as mineral, and also segregated it from the public domain and prevented its acquisition by others who might seek to acquire it under the agricultural laws. As the law now stands, the miner is given the preference, and he can ordinarily defeat any agricultural claimant even up to the time of entry for patent by making a valid discovery of mineral on the land in controversy. By doing away with the necessity of discovery, what will result? No longer is the mineral claimant afforded a convenient test as to the character of the land, which it is now within his power to make, but he must look elsewhere for the determination of the controversy. Who shall decide whether the land is mineral or agricultural in character, and how? Those who advocate the abolishment of this test overlook the fact that an agricultural claimant may file on the same land. They must offer some substitute which will not only work as well as the test which they seek to supplant, but to justify the change they should offer a better test. It may be that they have such a test in mind, though it is impossible that they can have one which has withstood the wear and tear of centuries as has the one they would discard—one which was created by the miners themselves.

Classification by Government

It has been suggested that the Government shall determine whether any particular tract of land is mineral or non-mineral. This means an intensive classification of the millions of acres comprising the 'public domain.' While this land is being classified, what is to be the status of mineral filings? And after it has been classified, what likelihood is there that in innumerable instances the actual character will be properly determined? Prospecting will then have become a 'lost art.' With the greatest respect and admiration for the splendid work that has been and will be accomplished by the government geologists, the writer feels that they would be the last to claim that they could perform such miracles. But it may be urged that the determination shall be made by the Government after the claim is filed on by the mineral claimant. One can imagine the delay and intervening uncertainty of title which would result if some prospector in a remote part of the public domain had to notify a government inspector of his desire to acquire title to a claim and had to await the arrival and inspection and confirmation of report of the government agent. The writer has personal knowledge of a case where the applicant had to wait two years for the government inspector's report on a patent application for a lode mine existing in a remote and mountainous region of California. This instance is not cited by way of complaint, but merely as evidence of what will inevitably be the condition if the burden of classifying the character of the land is shifted from the prospector to the Government. It means abandoning the right of the miner to deter-

mine for himself by discovery the character of the land he seeks to acquire and compelling the Government to assume the burden. And who is to pay the expense of such government inspection and determination? When the government inspector arrives on the ground will he not, in all probability, in the great majority of cases, base his determination of the character of the land on the same evidences that the prospector and miner himself ordinarily accepts as a sufficient discovery?

Legal Protection of Discoverer

Under the present law the prospector knows that as soon as he has made his discovery he is entitled to his ground and can enforce his right in the courts, where the long line of well considered decisions on the question of discovery will be followed. When discovery has been abolished, however, he can have no such assurance. The protection of the courts based on long established precedent is no longer his. The determination of the character of the land will rest elsewhere, and the miner will have sacrificed one of his strongest safeguards, founded on centuries of mining experience.

The element of discovery is firmly established in our system of mining law, as is evident from the following expressions of opinion by the Supreme Court of the United States:

"Discovery is the all-important fact upon which title to mines depends." (*Lawson v. United States M. Co.*, 207 U. S. 1, 13.)

"The whole scope of the chapter (Chap. 6 of Title 32, Rev. Stat.) is the acquisition of title from the United States to mines and mineral lands, the discovery of the mineral being, as stated, the initial fact. Without that no rights can be acquired." (*Creede and Cripple Creek M. & M. Co. v. Uinta T. M. & T. Co.*, 196 U. S., 337, 345.)

"In all legislation, whether of Congress or of the State or Territory, and by all mining regulations and rules, discovery and appropriation are recognized as the sources of title to mining claims, and development, by working, as the condition of continued ownership, until a patent is obtained. And whenever preliminary work is required to define and describe the claim located, the first discoverer must be protected in the possession of the claim until sufficient excavations and development can be made, so as to disclose whether a vein or deposit of such richness exists as to justify work to extract the metal. Otherwise, the whole purpose of allowing the free exploration of the public lands for the precious metals would in such cases be defeated, and force and violence in the struggle for possession, instead of previous discovery, would determine the rights of claimants." (*Erhardt v. Board*, 113 U. S., 527-535.)

The foregoing is sufficient to indicate that discovery has played an important part in the history of mining law of the world and is the most vital requisite of the law as it exists in the United States today. Not only is this fundamental requirement incorporated in the federal statutes, but practically every mining state in the West has enacted this provision into its supplementary statutes. If discovery be abolished, not only must the federal statutes be amended, but each

state will be compelled to alter its own statutes to harmonize.

The Law Now Well Understood

More important than all else, the mining laws with relation to each other, and with relation to all of our public-land laws, have, during the years of their existence, been interpreted by the courts; and we have now built up on these laws a superstructure consisting of a long line of decisions worked out after years of painstaking effort, harmonizing and correlating and unifying not only the mining laws themselves, but also these laws in their relation to the non-mineral public-land laws. Decisions involving the effect of discovery of mineral exist with relation to homesteads, town-sites, desert lands, timber lands, railroad lands, state lands, national forests, etc., and almost every imaginable problem that can arise where discovery is involved has sooner or later been presented and decided. This judicial interpretation of the effect of these laws with relation to one another is as important in its way as is the organic law itself which it interprets. It is more important in one sense, for the fundamental law may be enacted 'over night,' as it were, while the judicial interpretation and harmonizing of these laws is a matter of a great many years of laborious development.

*The law as it exists is now well understood all through the mining regions. Rights innumerable have become vested and are being exercised, and to make a radical change will materially unsettle conditions for years to come. To wipe out at one stroke all of these statutes and all of this superstructure of judicial interpretation will be a most serious mistake unless something materially better is offered in its stead. The burden rests heavily on the proponents of revision to establish this, for we are giving up the result of years of labor and cannot afford to take in exchange some substitute that somebody or other thinks will improve conditions, unless it is quite certain that it actually will have the beneficial effect claimed. We must have some valid reasons that cannot be satisfactorily covered by amendment to the existing law.

A Way Out

No one conversant with the facts can, however, fail to recognize that the existing mining law is deficient in many respects and has been stretched to cover conditions it was never intended to govern. This is particularly true in the case of a discovery requirement as applied to deep-lying oil-bearing strata, zones of secondary enrichment constituting the so-called 'copper porphyries,' and gold placers of Alaska where the 'pay streak' can only be reached by sinking through many feet of frozen overburden. To such deposits the rigid discovery requirements should not apply. But, on the other hand, because the law as to discovery has imperfections is no reason for abolishing it *in toto* unless its shortcomings are incurable by amendment.

This entire condition can be remedied very simply by

applying to such exceptional cases the following equitable doctrine which has already been announced many times by the Supreme Court of California:

"If a qualified person peaceably enters upon public lands of the United States for the purpose of discovering oil or other valuable mineral deposits therein, and such land is at the time unoccupied, and there is at the time no valid mineral location or lawful entry thereon, under the land laws of the United States, such person has the right to continue in possession so long as he continues to occupy the same to the exclusion of others, and diligently and in good faith prosecutes thereon the work of endeavoring to discover such mineral therein." (Smith v. Union Oil Co., 135 Pacific Reporter, 966-967, and cases cited.)

The citation from Erhardt v. Boaro, already quoted, is also an announcement of the same doctrine by the Supreme Court of the United States. It is true that some courts have limited the locator's right prior to discovery to his *pedis possessio*, or ground that he actually has in his physical possession,⁶ but it would seem that this is taking too narrow a view of the situation where the locator is using due diligence in perfecting a discovery. The United States, through its mining statutes, has extended to him a tacit invitation by declaring that all of its mineral lands are "free and open to exploration and purchase." When he enters upon such lands in good faith, intending to demonstrate their mineral character by making a discovery with reasonable diligence, the Government should protect him to the extent of his located boundaries of lawful size and thereby prevent acts of violence and unseemly contests in a struggle for possession.

The California doctrine is clearly the equitable one, and if there is any uncertainty about its being the law, it can readily be codified by Congress as an amendment to the mining statutes. This will overcome many of the objections to the rigid discovery requirement.

Mineral Versus Agricultural Lands

There is another objection which has been raised against the existing law by reason of the possibility of agricultural filings being made on such lands containing deep-lying mineral before the mineral claimant has had a chance to make a discovery. The remedy for such cases is clearly one which has already been utilized in the oilfields and in the case of copper porphyries.⁷

Where such areas have been satisfactorily demonstrated by adjacent indications or discoveries of mineral to contain, in all probability, the continuation of such deposits, the land department can withdraw them from agricultural entry for a sufficient period of time to enable prospective mineral claimants to demonstrate the actual presence of mineral by discovery. Under existing law the Government can in this way extend every protection to the miner. The pos-

⁶Hanson v. Craig, 170 Fed., 62; Gemmel v. Swain (Mont.), 72 Pac., 662.

⁷34th Ann. Rep., Director U. S. Geol. Surv., p. 154; also, Bulletin 537, U. S. Geol. Surv., pp. 40-41.

sibility of serious difficulty from an agricultural claimant prior to discovery is rather remote even in the absence of a withdrawal from agricultural entry. The agricultural claimant must file his application under the land laws in the land office, and the miner has every opportunity of calling the land department's attention to the probable mineral character of the land by protest. The department has in several instances already decided that it is not necessary that there be an actual discovery of mineral on the land in order to cause it to deny the agricultural application or withhold determination pending discovery work by the mineral claimant. Adjoining indications of mineral are sufficient to justify the department in taking such action.⁸

The experience of 'scrippers,' homesteaders, and other pseudo-agricultural claimants in the oilfields is evidence of the fact that the Government will not permit land with mineral indications to be patented under the non-mineral laws. If this protective action has not been exercised widely enough, it is possible to extend it simply by convincing the land department of an existing necessity. The miner's status can be further strengthened, if deemed necessary, by appropriate legislation.

It will appear from the foregoing discussion that to do away with the necessity of discovery is to amend our mining law fundamentally. It shifts the power of establishing the character of the land in the first instance from the miner himself to the Government. Whereas the miner has in the past been given the preference, wherever he could establish a valid discovery, any alteration in the law such as proposed gives rise to new and unfathomed complications. Where agricultural claimants assert title to the same land, and where national forests are involved, the miner is not likely to profit by doing away with discovery. Under a new law placing the determination of the question of mineral character in the hands of others, he may awaken to the fact that he has "sold his birthright for a mess of pottage."

It may be that the difficulties pointed out can be overcome and that some one can suggest an alteration of our mining code, fitted to our conditions, which will not work a hardship on the miner. But the old adage must be kept in mind that it is easier to tear down than to build up. The proposal of abolishing the extralateral right also deserves careful consideration, but the subject is too large to be dealt with in this article.

To guard against sudden invasions of rebel bands at the El Favor Mining Co.'s properties in Mexico, the principal buildings were surrounded by a high wall and towers from which a defense could be made. A little tact with the 'insurrectos' has at the same time been of great benefit to the management.

⁸Skinner v. Fisher, 40 L. D., 112, 116; also, see an unreported decision appearing in the *Mining and Scientific Press* of July 27, 1907, p. 123.

Bisulphite Zinc Process

The Metals Extraction Corporation, Ltd., has been conducting experiments with a process designed to treat mixed sulphide and tin ores. A 25-ton plant has been in operation at Swansea, and experimental work has also been under way in Wales, Tasmania, and Sweden. At the company meeting held in London, December 29, H. T. Durant gave the following particulars.

"If one traces from its inception the bisulphite process, we find that its evolution has been strikingly similar to, and by no means slower than that of other metallurgical discoveries. The bisulphite process has always appealed strongly to all metallurgists after the briefest explanation of its claims and objects, for the reason that nothing but water and power is required for its operation, and its chemistry is simple and does not admit of discussion. Briefly, the process consists in roasting ores containing, among other valuable metals, zinc. During the actual roasting there is given off certain impure acid gases; these latter are dissolved in water, and the acid water thus produced is used to dissolve the zinc out of some of the already roasted ore, producing, on the one hand, ore free from zinc and, therefore, now of value for its other contents (for example, lead and silver), and, on the other hand, solution containing zinc, which zinc is recovered as zinc oxide by the agency of heat. The work naturally divides itself into three distinct sections, namely: (a) roasting the ore; (b) dissolving the zinc out of the roasted ore by means of the acid gases given off during the roasting, and thereby producing ore free from zinc and also zinc solution; and (c) recovering zinc oxide from the above-mentioned solution.

"None of the standard types of furnaces met our requirements until we had succeeded in evolving a furnace of our own, simpler than any of the standard roasting furnaces and free from royalties or other encumbrances. We had to provide for roasting complex ores under certain well defined conditions; such complex ores (because, to a great extent, a drug in the market) had not previously been commercially roasted. The first means employed was to obtain the pure acid out of the acid gases given off during the roasting of the ore, then to stir the ore in closed vessels with water, and pump the acid into it, thereby dissolving the zinc. This procedure was abandoned for several reasons: it is sufficient to state one, namely, that up to the present it is not possible to make a pump which will pump the acid gas. The next method tried was an improvement in that no pumps for acid gas were required; this method succeeded metallurgically, but we had to abandon it because the smell of the acid solutions was such that it was impossible for men to work on the plant. Here we succeeded metallurgically, but failed from a humane point of view. Now, by certain plant modifications, involving none of the previous disabilities, we have succeeded in putting the process to work on a commercial scale."

Tin Mining in Bolivia

By G. W. WEPFER

The following notes are extracted from studies, and observations made in Bolivia together with information which I have taken from the work of Sr. Pedro Aniceto Blanco, entitled 'Monografie de la Industria Minera en Bolivia,' published in La Paz, 1910.

Pedro de la Gasca founded the city of La Paz in 1548 and this date may be taken as the beginning of the mining industry in Bolivia, the 'Peru alto,' of the Spaniards. They had undisputed sway until 1781, when the Indians rose in revolt from Cuzco, Peru, to Tucuman now in the Argentine Republic. In 1805 a new Spanish army returned to Bolivia to reconquer the lost provinces, but after twenty-four years had to give up the attempt. During this period mining was being intermittently conducted in different parts of the country.

The Spaniards were not seeking tin: they wanted only silver and gold. They found tin in many of their silver mines, tin veins frequently running parallel with the silver veins, sometimes being intertwined with veins of silver in such condition they could not be mined separately. As far as possible, the early Spanish miners avoided the tin ore, but now the conditions are reversed and in the same mines the silver ore is left in place and the tin is mined.

Where the tin ore is in the form of oxide as cassiterite SnO_2 , it is crushed, concentrated, sacked, and shipped. Where it is in form of sulphide, as franckeite, $\text{Pb}_2\text{Sn}_2\text{Sb}_2\text{S}_{12}$ or $2\text{PbSnS}_3 \cdot \text{Pb}_2\text{Sb}_2\text{S}_8$, it is crushed dry, roasted and leached with hyposulphite of calcium and the tailing is concentrated. The hyposulphite solution is precipitated and this silver precipitate is washed, dried, and sacked. The tailing is classified by spitzkasten, the spigot discharge goes to jigs, the overflow is again classified into sand and slime and treated on sand and slime tables. The jig middlings are reground, separated by spitzkasten again into sand and slime and run over sand and slime tables. According to the ores, separate concentrates can be obtained of tin, gold, copper, lead, and antimony.

I have the detailed records of 115 tin mines, and there may be as many as 25 more tin prospects. These 115 tin mines may be divided into three classes, viz: 44 are good mines, some of which requiring more capital to operate; 27 are financially embarrassed and able to do but little development work on their tin veins; and 44 are prospects. Bolivia has nine departments, but only in four departments, namely, La Paz, Cochabamba, Oruro and Potosi are tin mines to be found. To afford a general idea as to the condition of tin mining in Bolivia, I give herewith the detailed operations of a number of the better and larger tin mining companies.

Department of La Paz

The Sociedad Anónima de las Minas Huaina-Potosi y Milluni has 653 hectares of mineral land (1 hectare=10,000 square metres=2.4711 acres) on which are about 20 veins of tin and bismuth with an average content of 5 per cent tin. The monthly production amounts to 1000 Spanish quintals, (1 Spanish quintal=101.4 lb.) of concentrate of 55 to 60 per cent tin. The Company employs 200 men at a daily wage of 1.20 Bolivianos to 2 Bolivianos (\$0.60 to \$0.80). Bolivia has an agreement with the Bank of England whereby the bank accepts $12\frac{1}{2}$ Bolivianos for £1; 1 Boliviano equals about \$0.40. The Company has a good concentrator, also good houses for officers, and miners. The property is $12\frac{1}{2}$ miles by a good wagon road from La Paz.

The Mina Kala-uyu property consists of 450 hectares in the mountains of the Autajahua and Pacolla, Cercado province. The veins contain 10 per cent tin. The ore is stannite $\text{Cu}_2\text{S} \cdot \text{FeS} \cdot \text{SnS}_2$. The production amounts to 800 quintals of concentrate per month of 60 per cent tin. The Company employs 20 men, who work by contract and receive 16 Bolivianos (\$6.40) per quintal. The Company has a good future, but will need \$50,000 to open a tunnel and build a concentrator, (at present the concentration is done by hand sorting by Bolivian women) and an aerial rope way to convey

the ore from the mine. The property is $9\frac{1}{2}$ miles from the railway from La Paz to Guaqui.

The Empresa Providencia property consists in 300 hectares upon the mountains of Chilaya and Chun-chumany. This property has 40 veins which average 10 per cent in tin. The production varies between 150 and 200 Spanish quintals of concentrate of 68 to 72 per cent tin; employs 30 men at a daily wage of Bs. 1.20 to Bs. 2.50 (\$0.48 to \$1.00), and has a small concentrator,

wide and of an average content of 8 per cent. At the intersection of veins, the ore assays from 40 to 50 per cent of tin and contains many fine large specimens of cassiterite. There are 20 veins of uniform size and grade in the property. On the property are lakes Guallatani and Kasiri. Lake Guallatani is 4920 ft. long by 1640 ft. wide and at an elevation of 16,138 ft. above the sea. This water will be used for power purposes. It has a fall of 1476 ft. and could develop power for many mines in the locality.

The mineral area of this Company consists of 213 hectares. This Company is new and has not yet completed its equipment. The reserve of 13 per cent tin ore in sight amounts to 200,000 tons. The capital of the Company is £280,000.

The Concordia property was first known as the Andes Tin Company and was organized in Boston, Mass., with strong capital. The property comprises 477 hectares of mineral ground in the vicinity of Santa Vela Cruz. The ores contain from 3 to 19 per cent tin and the production averages about 200 Spanish quintals from the veins and from old dumps, but it is expected to be greater as soon as the new installations are completed. The concentrator includes a stamp battery, Chilean mills, jigs, and Wilfley tables. The Company has a hydro-electric power-plant and about 70 men at present occupied in road making. The Company has warehouses at the railway station 'Eucalipto,' as well as at 'Caluyo,' which serve as deposits for material in transit to the mine.

and houses for staff and workmen. The Empresa de Estaño en Araca has 502 $\frac{1}{4}$ hectares at Viloco. There are two large veins each two metres wide which carry from 12 to 19 per cent of tin, and produce 2000 to 2500 quintals of 60 to 65 per cent concentrate of tin per month. These veins produce the beautiful large specimens of cassiterite, the finest in the world, which can be seen in the National Museum at La Paz. This company employs 225 men. A branch railway to the Viacha-Oruro railway would greatly benefit this Company and with additional capital the mines could have a much greater production.

The Monte Blanco property is in the valley of Guallatani of the Cordillera Quimza-Cruz at an altitude of 17,984 feet. The veins are as much as two metres

Department of Cochabamba

The Minas de Tucuhuma is an Argentine enterprise which controls 64 hectares mineral ground upon the mountains of Tucuhuma and Jatun-Kaka in the mountain range of Colcha. One vein is a metre wide containing 3 to 4 per cent tin. The main tunnel 'Escorial' is lined with hewn stone and affords access to all the interior workings. The production is 500 quintals of concentrate of 65 per cent tin. The mine employs 140 men who receive Bs. 2 (\$0.80) per day. There is a mill on the property, but for better work a wagon road, from the mine to Colcha, connecting with the railway from Oruro to Cochabamba, and more capital is required. The Santa Rosa Company has 35

50-TON TIN CONCENTRATOR, ANDES TIN CO., LA PAZ, BOLIVIA.

hectares upon the mountains of Huallacoechi and Tuesuhuma in the Canton of Coleha. There are two veins, 3 metres wide, containing 8 per cent tin. The property is in a state of development at present with a short tunnel 200 ft. long, and is expected to produce 500 quintals per month. The Company would be benefited by a concentrator and a wagon-road about 6 miles long from Tuesuhuma to Coleha.

The Berenguela Tin Mines, Ltd., own 50 hectares in the Berenguela mountains in the Canton of Coleha. Within this area are 2 veins in tin, each 3 metres wide, carrying from 3 to 4 per cent of tin. The actual production per month is 700 quintals of 64 per cent tin concentrate. There are 73 men employed with a total monthly expense of Bs. 1200. The work is restricted on account of the scarcity of water for the mill. Without this difficulty the Company could easily produce 1000 quintals per month.

Department of Oruro

Empresa del Socavón de Oruro y Dependencias is also known under the old name Compañía Minera de Oruro. It belongs to the Bank of Chile in Santiago and comprises 252 hectares. There are 10 principal veins of an average content of 6 per cent tin and 12 marcos silver per cajon. The tin occurs as sulphides and oxides. The monthly production consists in 1121 metric tons of 10 marcos silver per cajon and 7 per cent tin, the oxides of 336 metric tons, with equal con-

tent of silver and tin. The Company employs 770 men with a daily wage of Bs. 0.80 to Bs. 4 (\$0.32 to \$1.60). The various mines have commodious buildings for offices for the staff and men at Oruro and the mine. The property is two and a half miles by wagon-road from the city of Oruro. All the minerals are conveyed to the concentrator at Machamarea, which is 18 miles from Oruro by a branch railway. The sulphides are roasted and leached, and the tailings are concentrated. In the concentrator, 290 men are employed with wages between Bs. 1 and Bs. 4.50 (\$0.40 to \$1.80) per day.

The Compañía Minera de San Jose has 87 hectares of mineral lands northeast of Oruro at a distance of only two and a half miles from that city. The yearly production amounts to 4500 marcos silver, of 100 marcos per cajon and 4500 Spanish quintals of 55 per cent tin concentrate. The Company employs 500 men with average daily wages of Bs. 2 (\$0.80). The ores are sent to the Alantania mill in the province of Poopo on the Antofagasta Oruro railway.

The Empresa Huanuni de Penny and Duncan operates 193 hectares upon Pozoconi mountain. There are two companies at work, namely: the English company, Harrison & Co. and the Empresa Penny & Duncan. The ore averages 8 per cent tin and the monthly production is 2583 Spanish quintals of 70 per cent concentrate. The Company employs 768 men at an average wage of Bs. 60 (\$24) per month. This

VIEW FROM LOADING TERMINAL, BUILT BY TRUNTON IRON COMPANY.

Company has a large concentrating plant. There are also in the town of Huanuni for the different mines of this Company buildings for offices, the staff and the men. This Company has working arrangements with the English company.

The Compañía Minera el Balcón is an English company which operates 16 different important veins on Pozoconi mountain, Canton Huanuni, Cercado province. The ore averages 8 per cent tin. The production is 3570 quintals per month of 65 per cent of concentrate. The Company has 400 men who receive an average wage of Bs. 1.80 to Bs. 4.50 (\$0.72 to \$1.80) per day. This enterprise is one of the best in the department of Oruro and has the best of equipment. The first-class ore is hand sorted to a grade of 55 per cent and sent to Europe for sale. The low grade is sent to the El Balcón mill where a 65 per cent concentrate of tin is produced. The transport of the ore from the Cataricagua mine is effected by an aerial ropeway with a capacity of 3550 quintals per hour, to El Balcón mill. A branch railway from Huanuni connects with the railway station Machamarca, which is of great service to this Company and others in that locality.

The Compañía de Estano de Anteguerra property comprises 227 hectares with two principal veins and many branch veins. The Esperanza group is on the Chunchu mountain and produces 500 quintals of 70 per cent concentrate. The Company employs 150 men who receive an average wage of Bs. 2.50 to Bs. 3.45 (\$1 to \$1.38) per day, and 12 men with a monthly salary of Bs. 200 (\$80). The Empresa Avicaya is a company operating a property in the mountain Chuallagrande in the province of Paria, 65 miles from Oruro with a 6-mile wagon road to the station of Pazna. The holdings of the Company cover an area of 300 hectares and the ore assays as high as 40 per cent, but the average is about 17 per cent tin. The monthly production is 3500 quintals of 70 per cent concentrate. The mine shaft is 656 ft. deep. An aerial ropeway 8200 ft. long brings the ore from the mine to the mill. There are between 500 and 600 men employed. Near by are other companies with equally good prospects, but they are doing nothing on account of lack of funds.

The Empresa Magariños property consists of 110 hectares on Villacollo and Sillacollo mountains with an average of 20 per cent of tin, and at the intersection of veins as high as 30 per cent. The production is comparatively small and irregular on account of lack of funds, but 500 quintals of 65 per cent concentrate per month could easily be produced.

Department of Potosi

The Empresa Soux Hernández, on Mount Potosi, has 10 tunnel mines employing 945 men who receive Bs. 1 to Bs. 2 (\$0.40 to \$0.80) per day. In the year 1909 this Company produced 385,350 quintals. Other properties of the Company which were worked by 187 men, produced 7700 quintals with an average content of 30 to 40 per cent tin. The Company has the large

modern mill Velarde and an aerial tramway to transport the ore from the mine to mill. Besides this mill the Company operates the Huailahuasi, Quintanilla, and Pampa mills which employ 1187 men, who receive an average of Bs. 1.50 (\$0.60) per day.

Production and Wages

The Bebin Hermanos are operating five mines with 570 men, who receive Bs. 1.50 to Bs. 1.60 (\$0.40 to \$0.64) per day. The mines produce silver and also about 2500 quintals of 50 per cent concentrate of tin per month. The Company has 10 other properties which are not being worked and the modern concentrating mills Huayra and Santa Rosa.

The house of Metting is working six mines and has five others in reserve. The production is 586 quintals per month of between 45 and 55 per cent tin. There are the two mills, the Candelaria and Alantaña employing 70 men who receive Bs. 1.40 (\$0.56) per day. These mines of Eduardo la Iglesia have a good future. These comprise seven properties, but only two, the Milagro and La Patria are being worked. In the Milagro 58 men are employed at an average wage of Bs. 0.80 to Bs. 1.60 (\$0.32 to \$0.64). The production amounts to 200 quintals per month. La Patria with 80 men and the same wages produces 400 quintals. The Patria has the Laguacayo mill and the Milagro mine has the Milagro concentrating plant.

The Cosme Alurralde Co. is one of the best mining companies on Mount Potosi and has 11 mines, but work is only carried on for the present at the Rosario property. The production amounts to 417 quintals of concentrate per month of 50 per cent tin and some silver. The Company employs 340 men, who receive Bs. 1 to Bs. 2 (\$0.40 to \$0.80) per day. At present the ore is hand-sorted.

Vladislavichy y Cia. has two mines and three mills which produce 642 Spanish quintals of 50 to 55 per cent concentrate of tin per month with 95 men. This Company has a good future. Tomas Elio has four mines and the Escalante mill which produces 400 quintals of 57 per cent tin concentrate per month. Primitivo Calvimonte has two mines and the Golpeadero and San José mills. He is working 134 men and produces about 420 quintals of 60 per cent tin concentrate. Matias de Mendieta has the two mills Chaca and Esperanza at Rivera and with 93 men is producing 1000 quintals of 55 per cent tin concentrate per month. Roman Lopez owns the Victoria and San Felipe mines and employs 120 men. The property produces 420 quintals of 50 per cent tin concentrate.

La Salvadora which belongs to Sr. Simón I. Patiño, has four hectares on the Juan del Valle mountain in the canton of Uncia and a mill which is considered the best and most complete in Bolivia; the work throughout is conducted upon best practice by careful and efficient engineers. The content of the ore fluctuates from 1 to 75 per cent tin. The mine has a depth of more than 960 ft., all of which is being exploited, using

electric rock drills with good results. The ore is raised by electric hoists, the electric power is produced at the Mira-Flores mill. The ore is conveyed from the mine by an aerial tramway 12,344 ft. long to the mill and can deliver 1500 to 2000 quintals in 12 hours. The production is 17,000 quintals of 65 per cent tin concentrate, and 3000 quintals of ore which needs no concentration, as it assays 57 per cent tin. The mine is dry and the levels are well ventilated by electric fans. A gas engine of 350 horse-power is installed to produce the electric power at 2300 volts which is reduced by transformers to 500 volts for the hoist, and to 220 volts for the rock drills and fans. In mine and concentrator everything is done to promote the welfare and hygiene of the men. There is a hospital and a school for the children.

The Compañía de Unica has been acquired by Sr. Simón I. Patiño for the sum of £150,000 cash. This was an Irish company conducted by the well known engineer, Sr. Juan B. Minchin, situated in the Chaya-guena mountains of Unica and consists of the following groups: Carmen with 12 hectares, Industria with 15 hectares, San Antonio with 12 hectares, Pizarro with 7 hectares and San José with 12 hectares. Sr. Simón I. Patiño has now two large mines, namely, the 'La Salvadora' and the 'Compañía de Unica' and will soon be able to produce 25,000 quintals per month of 62 per cent concentrate, by means of the Victoria mill of La Salvadora.

The Compañía Estañífera de Llallagua is owned by Santiago interests. It has 212½ hectares in Llallagua mountains. The Company has two large veins, the La Blanca and the San Fermín. It is 2296 ft. from the portal of the Azul tunnel to the La Blanca vein and from thence 1476 ft. to the San Fermín vein. From this tunnel a winze is sunk about 100 ft. to the new Cancañiri tunnel and from the Azul tunnel a raise is driven for 400 ft. to the San José tunnel. The Cancañiri tunnel is the principal tunnel, through which all the ore is extracted. All three tunnels have electric current for light, electric traction, and electric rock drills. The ore trains are pulled by electric locomotives. An aerial ropeway conveys the ore from the mine to the Chile mill, a distance of 16,400 ft. The production is 600 quintals per month, with 600 men. The wages are Bs. 3 (\$1.20) per day.

The Aramayo Franche y Cia. Ltd. property is one of the largest enterprises in Bolivia with headquarters at Quechisla, North Chichas. The Company has 3524 hectares containing veins of tin, bismuth, wolfram, and silver in the districts of Chorolque, Chocaya, and Tasna. The average assay of tin ore is 18 per cent and there are ore-pockets of cassiterite assaying as high as 70 per cent of tin. The rich material is hand-sorted for shipment to Europe. The Santa Barbara, Sala-Sala, and Cotani mills treat the Chorolque ore. For this district, the Company employs between 600 and 800 men and produces about 5000 quintals of 60 to 65 per cent tin. The Santa Barbara mill has an altitude of 15,777 ft.; the Cotani mill 13,133 ft., and the mines an

altitude of 17,188 ft. The ore from the mines at Tasna containing tin, bismuth, and wolfram are treated in the Buen Retiro mill. The Chocaya property has the Asllani mill at an altitude of 13,123 ft. The property is equipped with an aerial ropeway 9842 ft. long to transport the ore from the mines to the mill. There are 600 men employed at this property, producing 6373 quintals per month of 55 to 60 per cent tin concentrate. The yearly production of this Company is about 71,700 quintals of tin concentrate. The wages vary between Bs. 1.20 and Bs. 5 (\$0.48 and \$2) per day. At Quechisla, the Company has a new installation for the smelting of ores of bismuth and copper, an electric power and light service and good buildings for the staff and the men.

Gaylussite and Its Possible Utilization

By E. E. FREE

*Previous to the discovery by the Railroad Valley Co., gaylussite has been a rare and little known mineral. Museum specimens came from a small lake near Merida, Venezuela, and from Soda lake, near Ragtown, Nevada, at both of which localities the gaylussite occurred as scattered crystals with trona and other soda minerals. The mineral has also been identified at Searles lake, California, and in Sweetwater valley, Wyoming. It can be produced artificially, and is occasionally an accidental and minor by-product in the manufacture of caustic soda. Previous to its discovery in Railroad valley, it had been found by the Railroad Valley Co. as crystals scattered through the clays underlying the Dixie salt marsh and the Columbus marsh, Nevada. Physically it is colorless and transparent when pure, but is usually rendered yellowish or grayish by included clay. Crystals from the buried bed in Railroad valley are the purest and most transparent yet obtained. The crystals belong to the monoclinic system. It is very brittle, has a specific gravity of nearly 2, and a hardness of 2 to 3. Chemically it is a hydrous double carbonate of calcium and sodium, having the formula $\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$. In percentage composition the pure mineral contains 35.81% of sodium carbonate, 33.78% of calcium carbonate, and 30.41% of water. It may be distinguished by brisk effervescence with dilute acid, and by the fact that when boiled with water it decomposes, giving a white powder and a strongly alkaline solution.

The practical interest of gaylussite lies in its content of sodium carbonate. Sodium carbonate, known commercially as soda or soda ash, is largely used in glass and soap making, in the paper and textile industries, in the manufacture of borax and in many other industries. At the present time nearly all the soda consumed is made from common salt by complicated and expensive processes, the industry of its preparation being one of the most important branches

*Abstract from report of the Railroad Valley Company.

of chemical manufacture. Commercial soda ash is commonly sold on the basis of 48%, referring to a content of 48% of the hypothetical sodium oxide, Na_2O . This 48% soda ash is now quoted in New York at \$13.50 to \$14.50 per ton of 2000 lb. Pure gaylussite contains the equivalent of 43.62% of commercial, 48% soda ash, and carries, at the present average price, a soda ash value of \$6.11 per ton.

Methods of Treatment

Since gaylussite in quantity is a recent discovery, it has never been used commercially for the manufacture of soda ash and no commercial methods have been worked out or tested. However, laboratory results indicate no probable difficulty in securing such methods. Two alternative processes at once suggest themselves, and both have been tested and found satisfactory on a laboratory scale. The first would calcine the gaylussite to drive off the water, leaving a mixture of sodium carbonate and calcium carbonate, from which the former could be extracted by leaching. The second would grind the gaylussite and boil it with water, when decomposition would occur, the soda would go into solution and the calcium carbonate fall as insoluble sludge. It is impossible to be sure that either of these methods would work satisfactorily on a large scale and in the simple form stated, but no general difficulty is to be anticipated, and it seems probable that all difficulties of detail can be worked out.

Since there is no experience, it is not possible to give accurate estimates of the cost of manufacturing soda ash from gaylussite. However, by making use of the cost data of similar processes now industrially employed, I have estimated the probable cost of extraction by the first method above outlined as not over \$3.50 per ton of 48% soda ash, assuming fuel oil at \$1.50 per bbl. and a plant of such size as will produce 100 tons of finished product per day. This estimate includes all plant expenses, depreciation, etc., but does not include general overhead taxes or charges for land. It is based on the assumption that the gaylussite supplied to the plant will contain not more than 5% of clay or other impurity. It is believed that this estimate is too high rather than too low. The second process above mentioned is probably cheaper than the first, and with either process various cheapening expedients suggest themselves, such, for instance, as preliminary part calcination of the gaylussite by exposure to sun and air. It is probable that soda ash can be made more cheaply from gaylussite than from any other known raw material, even the natural sodium carbonate known as trona. In this connection, however, it must be remembered that the utilization of the soda beds at Searles lake, California, now being undertaken by the American Trona Co., does not depend on the value of the soda alone. The Searles lake deposit contains potash and borax as well as soda, and while the chemical processes to be employed in working this deposit will be much more complicated and expensive

than the process of working gaylussite, this fact is more than offset by the obtaining of three valuable products instead of one. I do not consider it probable that soda produced from gaylussite could compete with soda produced from Searles lake, so long as production from the latter point is not in excess of the capacity of the market to absorb the potash and borax produced as well as soda. The only by-product in the manufacture of gaylussite from soda ash is the calcium carbonate sludge, and, while pure calcium carbonate has some sale as whiting, it will probably be impossible to produce from gaylussite a material pure enough for this except at a prohibitive manufacturing cost.

Practically, the crucial point of the gaylussite question is one not yet mentioned, the cost of mining the gaylussite. It is apparent that a high cost of delivery of the gaylussite to the extraction works would more than absorb the margin of profit already none too large. Whether or not there is hope of devising sufficiently cheap mining methods for the Railroad valley deposit it is impossible to say until cores have been taken of the gaylussite beds, and we know more of their nature and purity. It is obvious, also, that any utilization of the Railroad valley deposit is dependent upon cheap rail transportation, both outward for the product and inward for fuel. Unless a railroad is assured there is no hope of commercial value in the deposit.

Gaylussite-Bearing Clays

Of some interest in connection with the buried gaylussite, is the discovery of a stratum of gaylussite-bearing clay immediately underlying the surface of the west central portion of the Railroad valley mud flat. The material covers sections 33 and 34 of Township 8 north, Range 56 east, and sections 2, 3, 4, 5, 8, 9, 10, and 11 of Township 7 north, Range 56 East, with parts of the adjoining sections, about 12 square miles in all. The gaylussite-bearing clay lies from 4 to 8 in. under the surface and is from 12 to 18 in. thick. Samples taken from 41 holes over this area show an average content of 13.82% gaylussite. The gaylussite crystals are usually in skeleton form and somewhat less pure than those from the buried beds, but are otherwise identical with the latter. Assuming an average thickness of 14 in. for the gaylussite layer and an average gaylussite content of 13.82%, the surface deposit contains nearly two million tons of gaylussite. It is probable that it could be worked for soda ash easily and cheaply and it would probably be of value as an adjunct to any soda or potash industry which might be established on the flat. The surface deposit is not in itself of sufficient size to encourage railroad building or determine a soda industry.

During October two dredges of the Orsk Goldfields Ltd. in Siberia treated 86,900 cu. yd. of gravel, yielding gold valued at \$38,000. Both boats were shut down from November 1 to 14 on account of bad weather.

Cylindrical Wooden Ore-Passes

By ANDREW FAIRWEATHER

*Recognition of all the defects in the square-set and cribbed types of ore-passes made it desirable to secure a design that would require no repairs. After mature consideration, it was decided to adopt a cylindrical pass made of stringy bark eucalyptus boards standing on end, the thickness to be varied according to the conditions. There was no lack of prejudice and opposition against the novelty, and even those who were prepared to push the idea were skeptical about certain things. But as progress is made in knowledge of the arrangement, the more convinced I am of its superiority over any other design for practically all conditions of stoping.

Construction

Briefly, the chute is made of stringy-bark timber staves, cut with beveled edges, and fitted in the form of a tube, the grain of the timber running vertical. The staves are bound together by double hoops of fence wire, until the waste envelopes them.

At first, sections were cut in the longest possible length, but varied from 5 to 8 ft. Staves varied in thickness from 4 to 10 in. Internal diameters of chute were 3 ft., 3 ft. 6 in., and 4 ft. The combinations of all these lengths and sizes made a large number of different stocks, and experience has decided against them. Now there are four standard types of chute:

1. Chute 10 in. thick, 4 ft. internal diameter.
2. Chute 10 in. thick, 3 ft. internal diameter.
3. Chute 6 in. thick, 3 ft. internal diameter.
4. Chute 5 in. thick, 3 ft. internal diameter.

The length of the staves is now universally 4 feet.

It will thus be seen that the length of stave is a standard; there are but three thicknesses, and two diameters, for reasons that are obvious.

Types 1, 2, and 3 are used in open stopes, type 3 in square-set stopes, and type 4 for effecting repairs to old cribbed passes which have failed. The following tables show the manner of employment in the open stopes:

VERTICAL PASSES, OPEN STOPES

| Height of chute, | 100-ft. lift. | 150-ft. lift. |
|-----------------------|---------------|---------------|
| 0 to 35 ft. | Type 1 | Type 1 |
| 35 to 70 ft. | Type 1 | Type 2 |
| 70 to 120 ft. | | Type 3 |

INCLINED PASSES, OPEN STOPES

| Height of chute, | 100-ft. lift. | 150-ft. lift. |
|-----------------------|---------------|-------------------|
| 0 to 35 ft. | Type 1 | Type 1 |
| 35 to 70 ft. | Type 2 | Type 2 |
| 70 to 120 ft. | (modified) | Type 2 (modified) |

In the square-set stopes the available space inside timber does not allow of any greater size than a 3-ft.

*Excerpt from paper read before the Australasian Institute of Mining Engineers and based upon experience at the Broken Hill South mine.

barrel, 6 in. thick. The type 2 (modified), mentioned in the table, for inclined passes, refers to a composite chute having a 10-in. bottom and a 6-in. top, and will be described later.

The staves to form the chutes are cut out of round or sawn stringy bark, of 10 by 5 in., 10 by 6 in., and 10 by 10 in. dimensions. The 10 by 10-in. piece is cut without waste, and to form the chute it is only necessary to reverse the ends of the two halves. Unfortunately, stringy bark shrinks considerably, so that if it is allowed to season at surface (and this is advisable if underground use has to follow), slightly different templates have to be used to form the true cylinder and to provide full bearing of the staves on one another. The shrinkage causes the use of an extra stave in the chute of 10 in. thickness, but only makes a slight alteration in size in the thinner sections.

It was recognized from the start that to obtain the best results the staves should be so placed that the rings of growth in the timber were parallel to the circumference of the chute. In a chute made of sawn timber this cannot be obtained, as in probably half the boards the grain would run parallel to the shorter side; consequently, an early attempt was made to use round logs. At first two cuts, inclined the proper amount toward one another, were made with the saw, and the outside and inside surfaces left rough.

As a guide to the timbermen, in assembling this type of chute, 4 dowel holes were bored in each stave, and $\frac{1}{2}$ -in. dowels used in the construction, as shown in Fig. 1. For the boring of these dowel holes a

FIG. 1.

template was used, so that the irregularity of the different logs was kept outside rather than inside the chute. However, experience proved that the time required to stand a section of this type was much greater than in the case of the sawn timber. The extra time was taken up in fitting dowels and closing up. As a consequence, the use of dowels was discontinued, and fencing wire was used to bind the logs, blocks being

used to fill up the irregularities. But this change meant that the timbermen had no guide for the correct placing of the logs.

The next move was to increase the number of the saw-cuts to three, that is, the two bevel cuts and one to form the inside face. This was an improvement, and gave the men a good opportunity to place the staves correctly, but as the rough, irregular surface outside effected no useful purpose, and gave some trouble in wiring, the saw-cuts were increased to four, and that method is now adhered to. The purpose of the sawing on both inside and outside faces is only to remove the irregularities and not necessarily to form definite angles with the other faces.

Advantage of Round Timbers

The advantage of the round timber is clear at once, apart from the fact that the correct position of the rings of growth, namely, that a smaller number of pieces go to form a ring than in the case of the sawn article; in the 3-ft. chute there is a reduction from 30 to 20 pieces, and in the 4-ft. chute from 38 to 24. A still greater advantage will be dealt with under the subject of costs.

The building of the chute in the stope is a simple and quick operation, although before it was attempted a good many had misgivings about it. The chutes on the South mine are formed of round logs, in cribbing form, for a height of about 13 ft. above the sill floor. On top of the round logs is placed a framed set consisting of four pieces of 10 by 10-in. Oregon pine, two of them dovetailed into the other two. On top of the framed set is placed a ring of 'chute blocks.' When fitted together the blocks form a foundation for the 4-ft. barrel, the outside of them being a polygon of eight sides, and the inside approximately a 4-ft. diameter circle. The blocks, in addition to being a foundation, are also a guide to the timbermen in the erection of the chute. They are spiked to the framed set.

Method of Building

The operation of building a section is as follows: One 4-ft. piece is stood on end, with its inside face flush with the inside of the chute block frame. One timberman holds it in position, while the other man gets another. The second piece is stood against the first, and the two are locked together by driving in a little timber dog. Both men then get to the job, one on one side and one on the other, standing other staves and working toward one another, using a dog to support each fresh stave to those already standing, and being guided in the approximate location of the staves by the chute blocks. When the ring is complete, two lengths of fence wire are cut, each length being a little more than twice the outside circumference. The wire is put twice around the chute, at a point 12 in. from the top, and the ends are connected by tying. This is also done at a point 12 in. from

the bottom. A fair amount of slack is allowed in each case. A hole $\frac{3}{4}$ in. diameter and 2 in. deep is bored in any stave, 12 in. from top, and a similar hole is bored 12 in. from bottom; into both holes a short waste piece of $\frac{3}{4}$ -in. round iron is driven, projecting about 3 in. The slack of the wires is caught up by a short drill, and twisted round the $\frac{3}{4}$ -in. pins. When both have tightened fairly well the chute dogs are withdrawn, and one timberman then goes round the chute hitting the staves on the outside with the back of his axe, while the other man puts the final strain on the wires by twisting. When the timbers have been closed up tight, the end loops of the wires are fixed in position by spikes driven into the stave. This prevents possible slackening. When the first section is finished, the second one is built on top in the same way, the lower barrel then forming a guide for the construction of the upper one. Of course, with all the staves being the same length, the surface of the top of the chute is flat. This lack of connection between two adjacent sections was thought at first to be a weak feature, but experience has shown that when the chute has been enclosed with filling there is no tendency to lateral movement.

Filling Around the Chute

An 8 or 9-ft. layer of filling is then distributed, particular care being exercised in spreading the waste evenly around the chute, and in not allowing it to build up high on one side only. This care is needed most with the thinner and, therefore, lighter sections: with the chute consisting of 10-in. timber, an advancing rill does not seem to have any effect in tilting.

As a rule, when the filling up is completed the tops of the chutes are found buried 12 in. under the surface. That is a desirable arrangement, as the stave ends are better protected from the effects of firing heavy holes in an open stope. There is also a better chance for sudden pressure, caused by a big fall of ground, to be distributed around the chute. As a further protection to the top section, two rings of bulk timber are sometimes placed around the top of the staves, the bottom ring flush with the top of the barrel, the upper ring flush with the surface of the filling.

As explained previously, at a point 30 to 40 ft. above the sill floor in an open stope a change is made from 4-ft. diameter to 3-ft. diameter chutes. To effect this change a framed set is used, measuring 3 ft. square within, and similar in construction to the larger one previously described. It rests on the lower barrel, and upon it is placed a ring of chute blocks, eight in number, the outside of them forming an 8-sided polygon, the inside approximating to a 3-ft. diameter circle. On top of this ring stands the 3-ft. chute, either 10 or 6 in. thick. Another method of making the connection between a 4-ft. chute and a 3-ft. chute is by means of a section 6 ft. long, and, in shape, a frustrum of a cone, with its staves so cut

that the bottom ends fit to form a 4-ft. ring and the upper ends fit to form a 3-ft. ring.

Inclined Passes

When the wooden cylinder was introduced, it was felt that repairs were a problem, if not an impossibility, and accordingly a rule was made that the barrels should only be reared vertical. This rule was found impracticable, and it has since been decided to use inclined chutes for the sake of economy and convenience, if possible, at the same grade as the dip of the walls enclosing the lode. As some of the chutes had failed at the point where the incline was commenced, the need of some special protection on the lower side of the pass was evident. The first suggestion put forward for the construction of the inclined pass was that it should be formed of round logs, of varying diameters, the large logs being placed in the lower half. This method has been used, and will be extended when certain alterations have been made in timber cutting and supply.

The existing method, however, consists in the insertion of $\frac{1}{4}$ -in. mild steel plate, 9 in. deep, between staves 10 in. thick, on the underside of the barrel. The plates are held in position by dowels, passing through holes bored near the outside edge and connecting the staves; two dowels of $\frac{5}{8}$ -in. round to each plate.

The action of the ore is to cut out a trough, about 1 in. deep, between adjacent plates. After that the plate edges carry practically all the dirt, and thereby protect the timber. No alteration is made in the cutting of the staves, to allow room for the plates; such alteration would only lead to confusion in selecting pieces. The upper half of the chute is formed of 6-in. staves, without steel ribs, but resting on arch-bars, bent to a curve of slightly less than 18-in. radius, and provided with 6-in. lugs. The bars are of iron 4 in. wide and $\frac{5}{8}$ in. thick, and are placed at the contact of adjacent barrels.

To provide a seating for the lugs, recesses 6 by 4 by $\frac{3}{4}$ in. deep are chiselled out of the top staves of the lower half—before the upper half is commenced. Fig. 2 illustrates the arrangement.

FIG. 2

The purpose of these bars is twofold; they act as a guide and support for the upper timber during construction, and they strengthen the chute against possible failure through heavy falls of ore.

Wherever a chute is changed from vertical to inclined, a definite angle is arranged for, not a gradual sweep. As is well known, change in direction means excessive local wear, and with a gradual sweep it is more difficult to provide against such wear than when an abrupt change is made.

The sketches below, Fig. 3, show how a change of direction is made, and also illustrate the mode of protecting the timber that would be ordinarily exposed to 'beat.'

FIG. 3.

The inclined chute is given its correct inclination by resting on an ordinary framed set 3 ft. square within, which is blocked up on one side by 10 by 10-in., as shown. The side openings, between framed set and top of vertical barrel, are closed by 10 by 2-in. laths, spiked to the 10 by 10-in. blocking and the framed set. Stretching across the framed set near its high side, and parallel with the 10 by 10-in. blocking, is a piece of 40-lb. railway iron, 3 ft. 10 in. long, with its ends resting in recesses 5 in. deep, cut out of the framed set, on two sides. There are five holes in it, 1 in. diameter, spaced 6 $\frac{1}{2}$ in. apart, in each a $\frac{7}{8}$ -in. shackle hanging, supporting another $\frac{7}{8}$ -in. shackle, which in turn supports a 7-ft. length of 40-lb. rail. The ore, in falling down the incline, strikes the railway iron and is diverted into the vertical chute. This arrangement is called a 'curtain,' and has been found to operate very satisfactorily. The loosely hanging fingers of this curtain yield to every blow, give no trouble in support, and cause the ore to fall vertical after the impact.

Making Repairs

In repairing, suppose, for instance, that three staves only in a ring have failed. The old pieces are removed and the filling behind them is worked away for an extra 6 in. or so to allow of the three new staves being placed in a position 6 in. behind their correct position, as shown in Fig. 4. These staves are cut 3 ft. 2 in. long, that is, 10 in. short, and each has a couple of spikes driven into it projecting toward the inside of the chute.

By pulling on the spikes in turn the three staves are drawn inward, the final tightening together is done by the timberman delivering blows with his hammer on the outside of the staves, operating his arm through the 10-in. space over the staves. When the closing-up process is completed, the space behind is filled with tailing and tightly rammed.

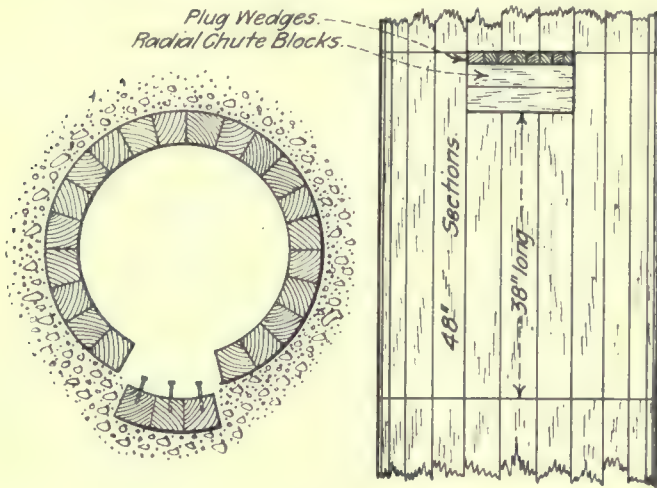

FIG. 4.

The description only covers a special case: sometimes the whole barrel has failed; in that case the complete ring is stood, except two staves, which are shortened and plugged on top, as shown. A closure has even been effected with one short stave only. If a number of sections have failed, naturally work commences on the lowest. The barrels are brought up as in the case of rearing them in an open stope, except that the final stave has to be dropped in. The only section giving trouble is the closing one, and that is dealt with in the manner just described.

Chutes in square-set stopes need scarcely any description, consisting merely of 6-in. barrels, 3 ft. diameter, reared in the set openings. They are constructed in a similar manner to those in open stopes, being bound with wire and packed around with filling. There is no blocking against the set frame and no outside lining to the set.

Minor Advantages of Chute

Apart from first cost, good wearing capabilities, and freedom from repairs, the cylindrical pass possesses the distinct advantage of being easily and rapidly withdrawn, after the stope is finished. This has been done in a large number of cases on the South mine. Generally through the pitching of the lodes, but sometimes by intrusions of waste, a chute has to be abandoned. An inspection of the interior will quickly show whether the timbers warrant removal. If so, a lump sum contract is set for taking out the timber and filling up the hole so formed. The *modus operandi* of recovering the timber is briefly to begin at the bottom, cut out the bottom section, fill up the height of it, remove the second section, fill up the hole again, remove the third

section and fill again, and so on till the stope above is reached.

The cylindrical chute has been found very serviceable and convenient on the South mine for the lining of winzes and waste passes.

Costs

The following table gives the cost of material and labor for the five types of cylindrical passes used, as well as for four other methods of construction used at various times on this field. Allowance has been made for bars, plates, fence wire, spikes, and nails, and timber has been reckoned at the following prices at present ruling in Broken Hill, namely:

| | Per 100 bd. ft. |
|--------------------------------|--------------------|
| Stringy bark (eucalyptus)..... | \$5.64 |
| Oregon pine, 10 by 10..... | 4.56 |
| Oregon pine, 10 by 2..... | 4.80 |

| No. | Type of chute. | —Cost per foot.— | | |
|-----|---|------------------|--------|--------|
| | | Material. | Labor. | Total. |
| 1. | 10-in. chute, 4 ft. diam..... | \$9.00 | \$0.72 | \$9.72 |
| 2. | 10-in. chute, 3 ft. diam..... | 7.08 | 0.72 | 7.80 |
| 3. | 6-in chute, 3 ft. diam..... | 4.22 | 0.36 | 4.61 |
| 4. | 5-in. chute, 3 ft. diam..... | 3.60 | 0.36 | 3.96 |
| 5. | 10 by 6-in. chute for inclines, 3 ft. diam. | 8.28 | 0.96 | 9.24 |
| 6. | Square set, lined 10 by 4 S. B. in- side and 10 by 2 Oregon outside. | 7.68 | 0.96 | 8.64 |
| 7. | Solid Oregon, 10 in. thick, made of 10 by 10, halved at ends..... | 11.40 | 0.19 | 11.60 |
| 8. | Bulk of 10 by 10 Oregon, spreaded with 10 by 2, and lined with 10 by 2 S. B. | 9.84 | 0.96 | 10.80 |
| 9. | 10 by 10 Oregon, 2-in. joggle..... | 9.12 | 0.19 | 9.30 |

Cost and consumption of supplies at the Mexican mill, Nevada, during the past year were:

| | Cost per ton. | Pounds per ton. |
|------------------------------|---------------|-----------------|
| Cyanide: | | |
| Mexican ore | \$0.495 | 2.00 |
| Monte Cristo ore | 0.287 | 1.17 |
| Lime: | | |
| Mexican ore | 0.034 | 4.02 |
| Monte Cristo ore | 0.039 | 5.26 |
| Lead salts: | | |
| Mexican ore | 0.044 | 0.41 |
| Monte Cristo ore | 0.119 | 1.06 |
| Zinc dust: | | |
| Mexican ore | 0.172 | 1.62 |
| Monte Cristo ore | 0.105 | 0.98 |
| Shoes and dies | 0.170 | 0.33 |
| Chilean rings and dies | 0.022 | 0.67 |
| Chilean screens | 0.011 | ... |
| Tube-mill liners | 0.038 | 0.89 |
| Pebbles | 0.095 | 7.33 |
| Fuel oil for heating | 0.163 | *3.69 |

*Gallons.

The Hyderabad mint, India, produced during the four-year period ending in 1910, 27,526,895 rupees, 2,171,069 half-anna, 114,562,382 2-pie. and 6,876,334 1-pie copper coins (12 pies equal 1 anna, 16 annas 1 rupee, and in Indian currency 1 rupee equals in U. S. currency 32.44 cents).

Duty is imposed on exports of rubber, tin, and wolfram from the Federated Malay States.

Leading Copper Producing States

For 1913 Arizona, with a record production, continues in first place among the copper producing states. The production for 1913, according to the United States Geological Survey, will greatly exceed the 359,322,000 lb. produced in 1912, and may exceed 400,000,000 lb. The Bisbee district will show a large increase over the 140,000,000 lb. of blister copper produced in 1912, the output probably reaching nearly 160,000,000 lb. in 1913. The Morenci-Metcalf district will not equal the 79,900,000 lb. produced in 1912, but the 1913 output will doubtless exceed 70,000,000 lb. The Globe-Miami district will show an increase of several million pounds over the 61,600,000 lb. produced in 1912. The Mineral Creek or Ray district made a large increase, the output for 1913 being approximately 50,000,000 lb., compared with 35,000,000 lb. for 1912. The output of the Jerome district will probably exceed the 1912 production of 31,680,000 lb. by a few million pounds.

The production of copper by the mines of Alaska in 1913 has been estimated by the United States Geological Survey at 19,700,000 lb. The decrease from the production of 1912 is due to the reduced output from the Copper River district, caused by the part destruction of the plant of the Kennicott-Bonanza mine and the consequent interruption of production. The production of copper from California for 1913 changed but little from the 35,835,000 lb. produced in 1912. As in previous years the largest output was from the Shasta county region, with important production from the foothill belt. The Shasta county district will probably show a slight increase over the 26,000,000 lb. produced in 1912.

Copper production in Colorado is largely incidental to the production of other metals, and the output will probably not change greatly in 1913 from the 7,963,000 lb. produced in 1912. The production of copper from Idaho for 1913 will show some increase over the 7,182,000 lb. in 1912. As in 1912, the main output was derived from the Coeur d'Alene and Alder Creek districts. Owing to the serious labor troubles in the Lake Superior district during the later part of the year, the production of copper from Michigan for 1913 was the smallest in many years. The output for 1913 was approximately 152,000,000, compared with 231,112,000 lb. in 1912.

The output of copper from Montana decreased from the 1912 production of 308,770,000 lb. The production for 1913 will probably be about 280,000,000 lb. As in previous years, the copper was derived mainly from the deposits of the Butte district. The production of copper from Nevada in 1913 remained nearly the same as that for 1912, which amounted to 83,413,000 lb. As in 1912, the Ely and Yerington districts were the principal producers. In 1912 the Ely district produced 67,400,000 lb. of blister copper and the Yerington district 14,700,000 lb. Both districts will show approximately the same output for 1913.

The production of blister copper from New Mexico increased largely over that of 1912, owing to the increased production of the Chino Copper Co., of the Santa Rita district. The output of copper in concentrates by the Chino company for the first three-quarters of the year was over 39,000,000 lb., indicating a production for the year of over 50,000,000 lb. The production of copper from Tennessee will show little change from the 18,395,000 lb. produced in 1912. As in previous years, the output came from the Ducktown district. In 1913 Utah made a large increase in the production of blister copper over the 132,150,000 lb. produced in 1912. As in previous years, the Bingham district was the principal producer, though the Tintic district made a considerable production and the San Francisco and other districts also contributed.

Studying Mine Fires by Experiment

The Bureau of Mines has recently built at its Pittsburgh experiment station an underground chamber or furnace in which to carry on experiments relating to mine fires and spontaneous combustion as occurring in mines.

A section of steel tube, cylindrical in shape, 61½ ft. in diameter and 27 ft. long, was laid on its side in a deep trench, and after lining this shell with fire-brick and mineral wool, and stopping the ends with 13-in. brick walls, it was covered with two feet of earth. The chamber was constructed so as to be as nearly airtight as possible, and in such manner as to retain to the greatest degree practicable any heat generated within its walls. At one end a motor-driven fan will blow in air at a rate which can be accurately measured, and at the other a stack is provided which can be opened or closed as desired. Through the top of the chamber, at frequent intervals, pass small pipes for withdrawing samples of air or gases and for inserting pyrometers for temperature measurement in the interior.

The chamber will hold six to eight tons of coal when one-third full. It is expected that different kinds of coal or of the gob or waste material from mines will be placed in the chamber and a study made of spontaneous development of heat in them under various conditions. After an active fire has been started in the chamber either by this means or artificially, experiments will be made on controlling the fire by reducing the air supply or by sealing it off entirely.

Investigations have been made in other countries, and to some extent also in this country, of the gases produced in actual cases of mine fires both before and after sealing off a burning area. The Bureau is now making, however, probably the first attempt to investigate such problems in an experimental apparatus which permits careful control of conditions and yet is on a scale nearly commensurate with mining operations. These investigations are being carried on by Horace C. Porter, chemist, of the Bureau of Mines.

While the immediate tests are with a view to questions met in coal-mining, the data derived will be available for solving problems connected with underground fires of all kinds.

Income Tax Regulation

Engineers will be especially interested in the following among supplementary regulations regarding the income tax, issued by the Treasury Department:

Expense for medical attendance, store accounts, family supplies, wages of domestic servants, cost of board, room, or house rent for family or personal use, are not expenses that can be deducted from gross income. In case an individual owns his own residence he cannot deduct the estimated value of his rent, neither shall he be required to include such estimated rental of his home as income.

In calculating losses, only such losses as shall have been actually sustained and the amount of which has been definitely ascertained during the year covered by the return can be deducted.

Persons receiving fees or emoluments for professional or other services, as in the case of physicians or lawyers, should include all actual receipts for services rendered in the year for which the return is made, together with all unpaid accounts, charges for services or contingent income due for that year, if good and collectable.

Debts which were contracted during the year for which return is made, but found in said year to be worthless, may be deducted from gross income for said year, but such debts cannot be regarded as worthless until after legal proceedings to recover same have proved fruitless, or it clearly appears that the debtor is insolvent. If debts due to the taxpayer and contracted prior to the year for which return is made were included as income in return for year in which said debts were contracted, and such debts shall subsequently prove to be worthless, they may be deducted under the head of losses in the return for the year in which such debts were charged off as worthless.

Amounts due or accrued to the individual members of a partnership from the net earnings of the partnership, whether apportioned and distributed or not, shall be included in the annual return of the individual.

Estimated advance in value of real estate is not required to be reported as income, unless the increased value is taken up on the books of the individual as an increase of assets.

Costs of suits and other legal proceedings arising from ordinary business may be treated as an expense of such business, and may be deducted from gross income for the year in which such costs were paid.

An unmarried individual or a married individual not living with wife or husband shall be allowed an exemption of \$3000. When husband and wife live together they shall be allowed jointly a total exemption of only \$4000 on their aggregate income.

Cover for Engineers' Note-Books

Engineers who have acquired the habit of neatness are often sorely dismayed at the external appearance and condition of their note-books. These become soiled, worn, and ragged by contact with moisture, the sun's rays, and rough rocks and other objects, both when in use in the field and while being carried in the pocket or in a shoulder bag along with other articles. The cover here described has been found entirely satisfactory, and can be quickly removed from one book and slipped on another.

DIMENSIONS AND PLAN OF COVER.

The cover is cut out of heavy linen-back mounted map paper, and then glued together with Le Page's glue, the cloth side being turned outward. The drawing shows the pattern and gives the dimensions necessary for the No. 363 Mining Transit Book of the Keuffel & Esser Co., which has dimensions of $4\frac{1}{2}$ by $7\frac{1}{4}$ in. However, the best plan is to cut off a piece of the paper and fold it about the book, then dress down as necessary, and finally glue together.

A is a slit in the inside front cover for the insertion of an Eugene Dietzen Co.'s No. 1925 scale-protractor. This is a combined transparent rule, scale, and protractor costing 20 cents, and is a most valuable accessory in the field.

B is a strip of emery cloth, $\frac{1}{3}$ in. wide, which is glued to the bottom of the outside back cover of the book—a most convenient place—for pointing hard pencils.

The smaller drawing represents a diagram to be placed on the inside back cover for taking slope angle in geologic work. A large size sewing needle is suspended by a silk thread from C. The note-book is placed on or in the plane of the slope to be obtained. The back cover is opened to allow the needle to swing freely to the vertical, when the angle of slope can be read. These protractor diagrams are sometimes blueprinted, and pasted in the backs of note-books.

Another use for the linen-back mounted paper is to make durable covers for paper-covered bulletins, books, etc., and it is a good idea to save the large scraps remaining from maps for this purpose. The original cover of the bulletin is removed. The mounted paper is folded about the book, cut to the proper size, and glued on in the same way as the original cover. The title page of the original cover is then cut out and pasted on the new cover.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

California Miners and the Exposition

The Editor:

Sir—What the Director of the mining exhibit says in the *Mining and Scientific Press* of January 3 concerning the character and importance of a suitable exhibit of the mineral industry will be universally commended by the mining public, and it is to be hoped that his appeal will meet an instant and favorable response. The opportunity is certainly unusual and not likely to be repeated within this generation, if ever. There has never been an adequate presentation of the state's mineral wealth. Great world's fairs are rare, and nothing short of one is likely to draw together the materials in sufficient variety. This being the case, we all ought to get to work to build up an exhibit worthy of the occasion and the country, in spite of the fact that there is no pecuniary reward in sight. While none besides promoters, stock-sellers, and private exhibitors are at all likely to make anything directly out of the fair, there should be sufficient incentive in state pride to bring about a united effort and creditable results. It would be a great pity if anything were left undone to insure a praiseworthy exhibition, both on the part of the mining fraternity and of the state.

From what has been said by Mr. van Barneveld, one may apprehend that a complete exhibit, if such could be had, would necessarily consist of two separate but closely related parts: namely, the display of ores and mineral products within the mining building, to be classified largely under county or local designations, and the other, a more systematic representation embracing processes and machinery as well as ores and products. The former will be splendidly housed, but in the nature of things the mill and cyanide apparatus, and matters of that sort, will have to be taken care of on otherwise vacant ground and amid less glorified surroundings. However, looks will hardly count. Space, and a methodical arrangement of processes and apparatus on a working scale, are much more to the purpose, and this view harmonizes with those of the Director. The presumed necessity of placing each collection under some geographical designation tends to lessen their effectiveness. Valuable historical and economic features are partly lost sight of unless the offerings are concentrated in the mass. This, probably, is unavoidable, but it would seem that the working part, if we may call it so, of the outside collections might be specially arranged from this point of view. This part of the exhibit must be

financed, it appears, by individuals, organizations, or districts.

The tentative program advanced by the exposition authorities looks to the installation of systematic exhibits far in advance of anything yet attempted at a world's fair, and if their project meets with the support it deserves, the result must remain unapproached for generations. Previous fairs, while not doing so much, have yet contributed good object-lessons, and their mineral displays have invariably been noteworthy. That of St. Louis was particularly so; but, like the rest, it lost much of its force and effect from the wide scattering of the exhibits, the better part of which was embraced within foreign collections necessarily shown as a whole. The best of these was the Japanese exhibit, in which were many noteworthy objects, arranged with exquisite taste. Among these may be mentioned the splendid relief map of the Ashio copper mine, which in itself was worth going to St. Louis to see. We have never produced anything to compare with the best foreign work, but there is no apparent reason why we should not, and as a beginning it might be well to try our prentice hands on a relief map of the Mother Lode region. Such a model would form a valuable addition to the fair, and might be presented by the five counties through which the famous lode runs, or by the property owners along its strike, who are numerous and prosperous enough to well afford it. This form of illustration lends itself very well to the surface features of extensive areas as well as confined ones, and furnishes an invaluable picture of the geological formations as well as the surface topography, and might be developed into an impressive exhibit of great scientific and economic significance. At the conclusion of the fair the work might be given over to some public institution, the State Mining Bureau, for instance.

The history of the mines of California is virtually the history of the state. Mining, therefore, has a great significance to the world, and its historical phase should by no means be neglected in preparing the exhibits. This state and neighboring states ought to be ransacked for historical objects. The ordinary tools of the old placer miners will, of course, be shown, and their cabins and places of employment and amusement ought also to be displayed. Antique arrastres and stamp batteries with wooden stems would find a place in such a collection. The educational side of such exhibits is measurably subserved by the ordinary glass-case displays, common everywhere. These serve well enough so far as they go, but it is important to complement them by systematic showings of metallurgical processes. If it could be managed to show visually how commercial metals are produced from the ore, the general public also would be instructed and impressed, as they cannot be by show-case exhibits of any size. There might be an attempt to show what we might call the evolution of the gold coin, for instance. This would naturally embrace a

mine, with men working; a hoisting works or tunnel; cars; a milling plant; cyaniding works or smelting works, or both; a refinery of some sort; and perhaps some minting process, all at work for so many hours per day or per week. With these would go, as the Director suggests, some piles of ore, and in descending ratio samples of the metal produced, by which the uninformed bystander could gather notions of the actual steps taken in mining and metallurgy when gold, silver, lead, or copper is won. This might not appeal to the miner or metallurgist, already educated to the saturation point in the details of his profession, but it would have an educational influence on laymen, whose ideas of mining need correction.

Efforts are being made to induce the different parts of the state to coöperate in their exhibits, instead of uselessly duplicating them. Groupings of the county exhibits may be advantageously made to this end, whose exhibits form a satisfactory unit. Thus the Mother Lode counties should unite in a first-class display, covering placer, quartz, and drift mining, together with the appropriate metallurgy. It should be practicable, also, to induce the copper-producing regions to combine likewise in a display of their peculiar arts. Very probably also, it might be found that the subsidiary or minor industries based on silver, mercury, chrome, magnesite, tungsten, etc., could make unit exhibits of merit. It is well worth trying. Pocket mining is another pursuit of much interest and its geology and practice might easily be shown graphically and instructively.

The proposal to put up and run a blast-furnace for smelting copper and lead ores is one of great importance beyond the ordinary and spectacular features of such work. It comes at an opportune time, since it will provide sulphur fumes for testing several promising devices for controlling or utilizing such products. The Cottrell, the Hall, the Thiogen or Young, the Field, and other processes might be tried exhaustively, to the no small advantage to the mining interests of the country.

HERBERT LANG.

Oakland, California, January 29.

Leaching Copper Ores

The Editor:

Sir—After reading the article in your journal of January 3, 1914, by Thomas T. Read, page 57, in which Mr. Read says "Hendryx agitator is to be displaced by Dorr classifiers when this plant is enlarged," I called up the office of the Bullwhacker Copper Co. and have been assured that they are well satisfied with the Hendryx acid-resisting agitator; that when the plant is enlarged more of the Hendryx agitators will be added, as they are giving perfect satisfaction, namely, ores ground to 30 mesh and containing from 2 to 4% copper, after 15 minutes agitation, 97 to 98% of the copper is in solution, and at 16 mesh 92 to 95%. I also notice on page 56, flow-sheet of Butte-Duluth plant

you show Hendryx agitator, and the flow-sheet of the Bullwhacker plant, you left out the Hendryx agitator, which should be just the other way about. Such inaccuracies in a journal of your character are inexcusable, to say nothing of their unreliability and false impressions given to the reader.

Will you kindly, in your next issue, correct the same, in order to be fair to everyone, which I believe to be the policy of your paper.

WILBUR A. HENDRYX.

New York, January 19.

[The information to the effect that the agitator was to be displaced came to Mr. Read through a source of information that had always proved reliable, and the announcement was published in entire good faith. Titles to the two cuts were transposed in making up the number, and while the mistake is annoying, any comparison of the figure and text makes clear at once what happened.—EDITOR.]

Ore

The Editor:

Sir—May I suggest the following definition of the word 'ore' as one satisfactorily covering the subject and avoiding grounds for the criticisms leveled at Mr. Rickard's definition by several of your correspondents: *Ore is rock whose metal content entitles it to consideration for the commercial production of that metal.*

Cost of transportation, difficulty of extraction, and the like, may prevent the present exploitation of a metal-bearing rock, but if it justifies serious consideration for that purpose, it is none the less ore.

JEROME B. LANDFIELD.

San Francisco, California, January 24.

Mining Costs at Joplin

The following table presents a detailed account of mining costs at a representative Joplin property. The average cost per ton of ore mined in the district is slightly higher than the figures presented.

| | |
|--------------------------|-----------|
| Labor | \$0.47900 |
| Explosives | 0.20400 |
| Fuel | 0.06870 |
| Water | 0.01455 |
| Oil | 0.00979 |
| Hard iron | 0.02478 |
| Drill R. & S. | 0.00802 |
| Drill steel | 0.00587 |
| Power R. & S. | 0.00441 |
| Other expenses | 0.01342 |
| Casualty insurance | 0.02037 |
| Superintendence | 0.02651 |
| Management | 0.02711 |

Total cost per ton\$0.90753

Imports of copper into Germany during the period January to November, inclusive, were 212,458 tons, of which 182,931 tons came from the United States. The consumption was 203,802 tons.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Carnotite contains potassium, uranium, and vanadium.

Crude iodine is prepared along the sea coast of Japan in six prefectures. It is reduced from seaweed, and in 1912 the output was 22,772 pounds worth \$44,979.

Six holes drilled by the rotary process in search of potash deposits, for the Railroad Valley Co. of Nevada, cost \$3500 each. They were put down from 745 to 1204 ft. through sand, clay, gravel, mud, and crystalline gaylussite.

The Minerals Separation flotation machine is made in five sizes, as indicated by the diameter of the stirrers, which revolve at 282 r.p.m., with approximately the following capacities per 24 hours: 12-in. stirrer, 70 to 84 tons; 15-in. stirrer, 140 to 168 tons; 18-in. stirrer, 200 to 240 tons; 21-in. stirrer, 360 to 430 tons; and 24-in. stirrer, 500 to 600 tons.

Converting copper matte at the Old Dominion smelter, Arizona, is done in the basic type of converter. The first was blown in early in January 1913, and remained on the stand until the middle of July. During that time it produced 14,500,000 lb. of copper before requiring any patching. No. 2 converter is making a better record than the first one.

Sycee is the name given to shoe-shaped ingots of silver weighing between 50 and 60 oz. each. The sycee at Shanghai at the end of 1913 amounted to 50,300,000 oz. Silver passes current as money in this form throughout the greater part of China, and having been prepared for this purpose at extra cost, naturally ranks at a higher value than silver in the form of large bars, as imported into that country. Sycee is part of the currency of China, and figures really as bank reserves. Sycee has been shipped and sold to India, and also to London, but such transactions are exceptional.

Transport of copper ore from the Mother Lode mines at Kennecott, Alaska, to McCarthy creek is done by means of a Leschen aerial tramway. The line is 6980 ft. long with a fall of 2564 ft. in that distance. This allows of the system being worked by gravity. The cables carrying the fourteen 6-cu. ft. buckets are 1½ in. diameter on the loaded side, and ¾ in. diameter on the empty side, are supported on 13 towers spaced 100 to 1500 ft. apart. The traction rope is ¾ in. diameter. The track ropes rest on saddles, and the traction rope is supported on sheaves or rollers attached at each end of intermediate supports. The whole sys-

tem is automatic in action, and only one man is required to supervise the line, which has a capacity of 50 tons of ore per 10-hr. day. An unusual feature of this tramway is that the towers on the upper part of the line are built upon solid ice that has become covered with broken rock. The anchorage at the upper terminal is also imbedded in ice which is said to be unusually clear. Another good use that is made of the system is the transport of supplies and mine equipment from McCarthy creek up to the mine.

Dredging in the Philippine Islands is on a fairly satisfactory basis. The boats are all worked by steam-engines. A crew of 1 white and 6 natives is employed each shift. Dredgemasters get \$150 per month, foremen \$4 per day, and natives 50c. gold per day. The Philippine Dredges, Ltd., is operating on the Paracale river. One boat is digging a considerable amount of mud and vegetation, and a shallow depth of gravel. The quartz cobbles from the boat are stacked on a barge, and then fed to a 5-stamp mill, which recovers about \$10 per ton by amalgamation.

Sizing tests of ore crushed through a 16-mesh screen at the Argonaut mine, Amador county, California, show the following result:

| Mesh. | Per cent. |
|------------------|-----------|
| On 40..... | 13.33 |
| 60..... | 16.67 |
| 80..... | 14.67 |
| 100..... | 9.17 |
| 150..... | 6.67 |
| 200..... | 5.83 |
| 300..... | 5.00 |
| Through 300..... | 31.66 |
| | 100.00 |

Discussing the treatment of tin ores in Cornwall, Edward T. McCarthy stated in the *Bulletin* of the Institution of Mining and Metallurgy that, bearing on the saving of tin, it has been clearly demonstrated in tin-dredging that where the black tin is crystalline and comparatively fine, it is fairly easy to save. The main factors governing the saving of the tin in this respect are: (1) plenty of area; (2) as low a gradient of the sluice-boxes as possible, compatible with keeping the material in suspension, and with the least possible amount of water almost to the point of allowing the material to bank; and (3) the saving surface to be of wood. A sample of black tin thus saved, and as sent to the smelters at Singapore from the Renong dredge in Asia, gave the following screening analyses:

| | | |
|--------------------------|--------|-----------|
| Total weight, grams..... | 525.7 | |
| Screen: | Grams. | Per cent. |
| On 30..... | 4.74 | 0.90 |
| On 60..... | 174.36 | 33.17 |
| On 80..... | 237.50 | 45.18 |
| On 120..... | 98.75 | 18.78 |
| On 200..... | 7.60 | 1.44 |
| Through..... | 0.95 | 0.18 |
| | 523.90 | 99.65 |

Special Correspondence

RENO, NEVADA

THE SAFETY FIRST CONFERENCE.—READING AND DISCUSSION OF VALUABLE PAPERS BY MINING, RAILROAD, AND ELECTRICAL WORKERS.—PRACTICAL DEMONSTRATIONS AND EXHIBITS.

One of the most unique and interesting meetings ever held in a Western state was the 'Safety First' Conference at Reno, on January 26 and 27. It was unique because it was probably the first instance in the country where a movement arousing such state-wide interest was started and carried to a successful conclusion by state officials. These included the State Industrial Commission of Nevada, and the Mechanical and Electrical Department and Engineers' Club of the University of Nevada. The meeting was interesting in that it brought together mine managers and miners, railroad officials and trainmen, power-plant superintendents and operators, members of the university faculty and students, state officials, labor representatives, engineers, and professional men. The total attendance was six hundred. It was productive of lasting benefit in that it focused the attention of the entire state on the Safety First movement, leaving as a record valuable papers and discussions.

The conference opened on January 26, in the University gymnasium, with W. E. Wallace, of the Brotherhood of Railroad Trainmen and state industrial commissioner, and James G. Scrugham as presiding officers. The following papers were presented at the afternoon session. 'The Safety First Movement in Nevada,' by John J. Mullin, secretary of the Nevada Industrial Commission. He described the organization of the commission, and dwelt on its future work, and the coöperation between employer and employee, that was necessary to make the movement a success. L. E. Abbott, safety commissioner of the Oregon Short Line, gave an interesting account of 'Safety First on the Oregon Short Line,' showing with what enthusiasm the work had been taken up, and what splendid results in the saving of life and limb had been accomplished on that railroad system. 'Safety First in Practice,' was discussed by Frank Ingram, secretary of the Brotherhood of Locomotive Firemen and Engineers. Mr. Ingram told of the safety precautions which had been suggested by the employees of the railroads in the state, dwelling principally on the law which the trainmen had succeeded in placing on the statutes of Nevada requiring locomotives to be equipped with 1500-cp. arc headlights. J. H. Linn, of Topeka, Kansas, gave a short description of the safety work on the Santa Fe system, and followed with an interesting paper on the student apprentice system of the Santa Fe, with which he is connected as assistant chief instructor. J. M. Guild, secretary of the Bureau of the Union Pacific, followed with a short description of the work on that road. H. P. Boardman, head of the Civil Engineering Department of the University of Nevada, made some interesting remarks on 'Safety in Civil Engineering.' He showed how necessary it was in designing structures to use proper safety factors, citing the Quebec bridge failure as an example where all the necessary precautions had not been taken. Two conclusions drawn from this failure were: (1) that a structure which might be satisfactory and safe on a small scale might not be safe when constructed in a similar manner on a much larger scale; and (2) that certain members of a structure may be subjected to greater strains during erection than after completion, thus necessitating corresponding greater strength. He also mentioned the necessity of automobile drivers exercising more Safety First precautions. A paper titled 'The Prevention of Accidents' by C. W. Price, safety engineer of the Wisconsin Industrial Commission, was read by the secretary, Mr. Price not being present. The paper

described some of the remarkable results that have been obtained among eastern corporations, and then gave in detail the necessary steps to be followed in introducing a Safety First movement in an industrial organization.

The evening session was devoted to a demonstration of wireless telegraphy, and of discharges of high potential electricity by the Department of Electrical Engineering and Physics of the University, followed by motion pictures of Safety First on the Union Pacific; The Manufacture of Steel, loaned by the U. S. Steel Corporation; University of Nevada Campus and Laboratory Views, and National Mine-Rescue Demonstrations, loaned by the U. S. Bureau of Mines.

Owing to the severe storm of the 25th and 26th, many of the delegates were delayed in reaching Reno, so the electrical

EXPLOSION OF COAL DUST AT EXPERIMENTAL MINE, BUREAU OF MINES, BRUCETOWN, PENNSYLVANIA, SEPTEMBER 23, 1913. ONE OF THE STUDIES THE GOVERNMENT IS MAKING IN THE INTEREST OF SAFETY IN MINES.

papers were held over until the 27th. On the morning of that day, an interesting meeting was held by railway apprentice instructors of the Southern Pacific, Santa Fe, Oregon Short Line, and Union Pacific. The meeting was presided over by Norman Collyer, executive secretary to the president of the Southern Pacific Railroad Co., and papers were presented by John Edwards Bray, Nevada State superintendent of Public Instruction, Thos. G. Gray of the Sacramento, and H. S. Gillette of the West Oakland shops of the Southern Pacific; Mr. Linn of the Santa Fe; and A. W. Preston, shop superintendent of the University of Nevada. On the preceding day, Mr. Collyer had addressed the engineering students of the university on the apprentice system for college men in operation on the Southern Pacific system. At the electrical section of the conference, on January 27, at which A. H. Babcock, electrical engineer for the Southern Pacific, presided, a discussion was held on 'Safety Regulations for Electric Power Companies,' the leading paper being by W. K. Freudenberger, chief engineer of the Nevada State Public Service Commission.

The principal session of the conference was the general meeting on the afternoon of the 27th, at which Governor Tasker L. Oddie presided. At this session, interest was mainly centred in the discussion on electric headlights, which was introduced in a valuable paper by J. G. Scrugham, professor of electrical and mechanical engineering at the University of

Nevada. Following the headlight discussion, after a demonstration of the 'talking' arc, the following papers were presented: 'Safety First in Mining,' by Thomas M. Fagan, president of Tonopah Miners' Union. He discussed in an eloquent manner the relation of the employee who sells his labor to the employer and the state, dwelling particularly on features of the Nevada Insurance and Compensation Act. 'Safety First at Nevada Consolidated Copper Company's Plant,' by Lindsay Duncan, mechanical engineer of that Company, was read by title in the author's absence. Edward Ryan, state mine inspector, gave an interesting paper on 'Accident Prevention in Mining,' paying particular attention to the necessity of educating employees to their own dangers. At the close of his address, Mr. Ryan demonstrated the miner's oxygen helmet and rescue outfit, also the pulmotor, which is used by the U. S. Bureau of Mines. A. W. Hunsinger, of the Goldfield Miners' Union, spoke on accident prevention, and was followed by the Rev. Lloyd B. Thomas, Carson City, Nevada, who gave his impressions as a visitor at the Safety Conference held under the auspices of the American Museum of Safety in New York, December 10-12, 1913.

At the close of the meeting, a communication from secretary Cameron, of the National Council for Industrial Safety, urging the formation of a local council in Nevada to cooperate with the national body, was read by C. W. Whitney. On motion of John J. Mullin, secretary of the Nevada Industrial Commission, a resolution was passed by the convention to the effect that it was the opinion of the conference that an organization be formed to carry on the industrial safety work in Nevada, and that Governor Oddie appoint a committee of nine, of which he constitute the chairman, to arrange for and perfect such an organization. The conference proper closed with a banquet given by the Engineers' Club of the University to the delegates and guests. A. A. Codd, regent of the University, presided as toastmaster, and the speakers of the evening included Governor Oddie; W. S. Lunsford, city attorney; P. A. McCarran, justice Supreme Court; R. J. Clancy, assistant general manager Southern Pacific railroad; J. B. Brennan, representing the Blacksmiths' Union; J. H. Linn, of the Santa Fe; and J. E. Stubbs, president of the University of Nevada. Mr. Clancy's remarks were particularly interesting to the technical and railroad men present, as they covered a wide range of the Southern Pacific's activities, touching on the historical side and closing with the live subject of electric headlights. Of the exhibits at the conference, the principal one was that of the Southern Pacific Railroad Co., which reproduced the exhibit booth that was shown at the International Exposition of Safety and Sanitation, held in New York City in December, at which time the Company was awarded the Harriman medal for the best safety record of all railway companies in the United States during 1913. The exhibit was in charge of John C. Weigandt, assistant chief clerk to Julius Kruttschnitt, chairman of the executive committee of the Southern Pacific Railroad Co. Another interesting exhibit was an electrically operated working model of the block signal system used on the Southern Pacific. The University of Nevada exhibited a small locomotive, gas engine, and generator, constructed in the University shops, also a comprehensive display of safety first literature. Much of the credit for the success of the conference is due to J. G. Scruggam, who conceived the idea of the meeting and arranged practically all its details, carrying it through with honor to himself, the University, and the state.

The Nevada State Mine Owners' Association met at Reno on January 28. Members were present from all parts of the state. An election of officers resulted as follows: President, John G. Kirchen, of Tonopah; vice-presidents, Albert Burch, of Goldfield, and C. B. Lakenan, of Ely; and secretary and treasurer, W. B. Alexander, of Reno. The executive committee elected was as follows: John G. Kirchen, Albert Burch, C. B. Lakenan, W. A. Bradley, Frederick Bradshaw, L. G. Campbell, and W. H. Bradshaw. At the conclusion of the

annual meeting, there was a dinner given at which the following were present among others: John G. Kirchen, W. L. Alexander, George Wingfield, Fred J. Siebert, Frederick Bradshaw, Albert Burch, W. H. Blackburn, Arthur Lowry, L. G. Campbell, Hugh H. Brown, and C. V. Jenkins.

LONDON

PHOENIX AND EAST POOL MINES.—LABOR TROUBLES IN CORNWALL, AND MINERS' OBJECTIONS TO NEW SYSTEMS.

A few weeks ago I mentioned that the Duchy of Cornwall had been trying to exact onerous terms for a renewal of the lease of the Levant tin and copper mine near Land's End. I explained that the Duchy of Cornwall was in by-gone days the private property of the King of England, but nowadays a government department. The treatment of the Phoenix tin mine, north of Liskeard in East Cornwall, has apparently been different. It was stated at the meeting of shareholders last week that the Duchy office had agreed to subscribe £7500 on mortgage, provided the directors found a similar sum. This money is required for further development. Royalty has a particular interest in the Phoenix mine, for did not the present King and Queen, when Prince and Princess of Wales, pay a visit to it for the express purpose of formally starting operations in connection with the sinking of the new shaft? At the most recent reorganization of affairs, in September, 1912, Bewick, Moreing & Co. were made managers. When they assumed control at Phoenix, they arranged for £50,000 new capital, for the purpose of paying off the debentures and liabilities, and providing funds for further development. It is evident that this amount has not been sufficient, otherwise new debentures would not now be issued. The property has afforded another example of the miner-like fashion in which the old Cornishmen conducted their operations, for it has been proved by the present managers that no ore worth extracting was left in the old workings. It has therefore become necessary to launch out into a vigorous scheme of development at a number of places in virgin ground, in the hope of finding sufficient ore to keep a mill going. The directors and managers are keeping rather quiet about the performance and prospects at this mine. The yearly report was not circulated to the press, and the meeting of shareholders was held privately. It was only accidentally that I heard that the report had been issued and the meeting held.

The same firm, Bewick, Moreing & Co., also has the East Pool mine, near Camborne in hand, and will have an equally difficult job there. For years the mine yielded handsome profits, and in recent times the crushing and concentration departments led Cornwall in the treatment of low-grade complex ore. But the yield per ton gradually fell, and in order to reduce costs development underground was neglected. Finally the provision of additional capital became imperative in order to conduct a new campaign of development. This, Bewick, Moreing & Co. undertook to do a year ago. Their efforts have given disappointing results so far. One of the objectives at depth was the finding of the Great lode. A lode, which is apparently that sought, has been cut, but it is low grade. At this mine, Bewick, Moreing & Co. have also had labor troubles, owing to their desire to keep track of costs more closely, and to abolish what is known as the contract system of pay, which is in general use in Cornwall. The men refused to go underground on the new terms and in the end, the regulations were withdrawn. Under the contract system, the 'taker' of the 'pare' or gang is paid the whole of the amount earned by the 'pare', and he distributes the money among the men and boys constituting it in such proportions as he may previously have agreed with them. The boys he usually pays \$12 to \$14.40 per month, and he justifies this low wage by a claim that he is teaching them their work, or in other words, they are serving a sort of apprenticeship for which he claims a part of the value of their services, as a payment for supervision and in-

struction. The manager of the mine has no control of the members of the 'pare', so far as wages paid or time worked is concerned, and frequently shifts are missed by one or other member without penalty. This is an unsatisfactory state of affairs, for the standing charges of the mine continue the same whatever the output, and it is necessary to get a maximum of shifts worked. The management of any mine is entitled to, and indeed ought to, know the rate of pay of all employees per shift, and how many shifts they work. The older men were opposed to any change that involved payment for actual shifts worked at a fixed rate, as their share for so-called supervision would vanish, and they were able to persuade the younger men to follow their lead. It is always difficult in Cornwall to abolish old customs; but it is hoped for the sake of the industry that the attempt will be made again, after it has been clearly demonstrated that the genuine worker would not be a loser by the adoption of the shift system of payment. Another difference with the men was the proposal to close all contracts on the 15th day, and at the end of each month. This would have resulted in two pays per calendar month, the Company only holding three days pay in hand instead of two weeks pay as at present, and would have replaced the existing four-weekly pay, with subsist at the end of the second week. The change was necessary to enable the general managers to figure their costs, etc., per calendar month. The opposition of the men was based on the opinion that this change would result in their only having 12 instead of 13 pays, an absurd contention in view of the fact that the men were to be paid on shifts actually worked.

NEW YORK

THE GUGGENHEIM EXPLORATION CO. AND ITS 'FRIENDS'.—AMERICAN SMELTING & REFINING CO.'S COPPER TRANSACTIONS.—TRUST INVESTIGATIONS.—COPPER STATISTICS QUESTIONED.—BRITISH COLUMBIA COPPER COMPANY.

Whatever the Guggenheims do is of burning interest to a great many people, and in the advertising they get by their 'loving' friends, not a little is ascribed to them which is more surprising to them than to anyone else. Whenever negotiations for a mining property are started anywhere, it is sure to be whispered, to the accompaniment of mysterious winks, that "the Guggenheims are back of it." The latest of these interesting canards is a despatch from Denver stating that the Guggenheim Exploration Co. is about to take over pretty near the whole Rico district of Colorado, involving a \$4,500,000 deal. Just how this could be brought about without the officials of the Company knowing anything about it is not clear, but it seems to offer no difficulties to the reporter. What the Department of Justice is going to do to the American Smelting & Refining Co. is another matter of much interest, in this case to business men in general. The hearings in the dissolution suit against the United States Steel Corporation still drag along, but do not even get space on the financial page any more, and it is clear that the public has lost all interest in the matter, being pretty well convinced now that the 'Steel Trust' is, at the worst, a beneficent ogre. The International Agricultural Implement Co. is also under scrutiny; but the worst charge that can be truthfully brought against these two big organizations is that they have combined a number of competing plants into one organization. So many intelligent men now believe that unrestricted competition is harmful to the public interest, that it seems doubtful whether any public support for the dissolution of the organization on that score alone can be evoked. What the Department of Justice has against the American Smelting & Refining Co. has not been made public, but must be much the same as the two others. Meanwhile the Company has been 'getting in wrong' to a further extent, for the statistics of 1913 show that it advanced to the leading position in the copper producing and selling business, a

position which it has long held in lead production. The Company sold nearly 500,000,000 lb. of copper in 1913, as compared with 442,000,000 lb. by its nearest competitor, the Amalgamated sales agency. The difference is really greater than this, for Braden copper goes directly to Europe, not appearing in the figures, while the Amalgamated agency sells much more copper for outside companies than the American Smelting & Refining Co. does. Whether this fresh proof of villainy on the part of the 'smelter trust' will add fresh fuel to the flames of governmental wrath remains to be seen. As a matter of fact, were it not for President Wilson's anti-monopoly policy, all three matters would probably be quietly dropped.

I have several times referred to the suspicion with which American copper statistics are regarded abroad, while consumers here similarly allege that the European figures are not to be trusted. The most vigorous attack on American statistics is one published in the *Ironmonger*, of London, which says: "American news is now entirely discredited after the last returns issued by the Copper Producers' Association, which are regarded by most as having been manipulated. If these present figures correctly represent the position, then it is held in many quarters that the preceding figures have not done so. Under the circumstances, the copper market took the returns calmly, although they were bad enough to have precipitated a panic, and the fact that prices did not sustain any greater deterioration than was actually the case, is probably due to the extent of the depreciation already sustained and to there being no bull account open worth consideration. The attitude of producers has not been such as to inspire any confidence in the trade, for there has been a continued weak appearance about prices and a decided tendency toward competition between producing and dealing interests, all of whom seemed to want to book business. Whether the chief producers have much metal on hand awaiting sale is not clear, but they are quite ready to sell, and are in a position to give early shipment copper whenever required, a somewhat unusual circumstance, in the light of the experience of the greater part of last year." Consumers here freely intimate that large quantities of copper have gone to Europe on consignment and do not appear in the statistics there. Pascal once said that we know truth not only by the reason, but also by the heart. In this case a good many people seem to be somewhat affected in both organs.

The British Columbia Copper Co. has been extending its operations for some time and has been busy exploring and optioning properties. It has done so well in this regard that Hayden, Stone & Co. have underwritten a new bond issue of \$1,000,000 in 6% convertible bonds, and it is reported that the \$3,000,000 company will be reorganized as one with \$5,000,000 capital. The refinancing plan will be announced during the current week. As a result of this activity, British Columbia shares advanced from \$2 to \$4 last week. The new smelter of the Granby at Anyox will not be blown in until after February 1, there having been some delay in the construction of a dam. The Mason Valley has had its converter department in operation for several weeks, two 12-ft. converters being in use. In addition to making a saving of about 1½c. per pound over shipping the matte to Garfield, the converters enable the Company to utilize 50 to 60 tons per day of silicious custom ore, of which there is an abundant supply. The Mason Valley should make a better showing this year. The suit of the United Zinc Co. of Maine against Sydney Harwood and others to recover \$1,000,000 excessive profits alleged to have been made by them when they were directors of the United Zinc & Lead Co. of New Jersey, has been dismissed by the Massachusetts Supreme Court. The fraud alleged was in the sale of Missouri lands to the New Jersey company, which was afterward merged into the Maine company. The Court held this merger was never authorized and the Maine company had no right to bring the suit.

General Mining News

ALASKA

CIRCLE

Clarence Barry has contracted with the Union Construction Co., of San Francisco, for a 3½-cu. ft. close-connected bucket-dredge, to dig 15 ft. below water-level. This dredge will be erected on Mastodon creek, near Circle City. Probably the most important feature in its design was the question of economy of power production. After making an exhaustive study of the problem both east and west, it was decided to install two R. Wolf locomobiles. These engines give a high economy in fuel consumption, delivering 1 b.h.p. per hour from 1.06 lb. of coal. The engines use superheated steam and are mounted directly on the boiler. The dredge will have a revolving screen, to remove the oversize material, the fine passing through the screen, directly into either of two sluices. The bucket-lines of both dredges will be made of cast nickel chrome steel with manganese steel lips.

FAIRBANKS

Since quartz mining started here in 1909, the total gold produced is approximately \$1,000,000, of which the Rhoads-Hall mine has yielded \$400,000. It is estimated that the 1914 out-

RHOADS-HALL MINE

put of the district will be nearly as much as the total previous production. During December the Newsboy mill was cleaned-up for \$2500, which is an equal amount short of all expenses at the mine and mill. Leslie M. Drury is manager. Good ore is now being mined. Gravel worth \$1.75 per foot has been uncovered by Johnson brothers and Johnson on 22A Goldstream. They have a 35-hp. plant on the claim, and will take out a large winter dump.

NOME

John Brower, Charles Mitchell, and J. L. Cole, of Nome, have contracted with the Union Construction Co. of San Francisco, to build a 3½ cu. ft. close-connected bucket dredge, to dig 35 ft. below water-level. It will be erected on Bangor creek on the Seward Peninsula. It will be operated by distillate engines and will have the standard equipment of winches, screen, stacker, and gold-saving tables. The distributor will be of the Company's special design, by means of which the fine material is spread equally over all the tables. This is a feature which has been neglected in most of the California dredges, resulting in about 10% of the gold being caught in the upper part of the first two or three tables.

SHUSHANA

Little work is being done on the claims just now, but about 400 cabins have been erected. Food is plentiful, including wild meat at 10c. per pound. Flour, beans, sugar, and rice are 50c. per pound. Several large outfits are on the way to the camp. A moving-picture outfit is in charge of Frank L.

Johnson. He is equipped to take and show pictures. G. P. Sproul, who has studied the different routes to Shushana, stated at Fairbanks that the Tanana river route is the best one under present conditions.

VALDEZ

The Cameron-Johnson Gold Mining Co. is to install an aerial tramway to convey ore from its Treasury Note claim to the mill built last summer. The Company has 26 claims on the right limit of Shoup glacier. Three adits have been driven in the Treasury Note, the veins being 18, 30, and 48 in. wide, respectively, worth \$185 per ton. Rich ore has also been opened in the Montezuma claim.

ARIZONA

COCHISE COUNTY

On January 22, excavating was started for foundations of the first unit of the Copper Queen concentrating plant. The site is just below the Sacramento shaft. This unit will be of 25-ton capacity to check laboratory work. Concreting the Junction 5-compartment shaft from 1800 ft. to the surface is practically finished. The first work was from 1500 ft. up, and then from 1800 to 1500 ft. It is likely that development will be resumed at the Denn. Water has been an obstacle in this mine. Better ore is being mined by the Higgins Leasing Co. Ore shipments are being sent regularly from claims at Tombstone, the State of Maine being the largest producer. Results of the examination of the Tombstone Consolidated mines by engineers of the Phelps-Dodge company have not been published yet. The Commonwealth Extension, at Pearce, has been sold to Bisbee mining men.

A 'Safety First' smoker was held last week at Bisbee, at which over 700 men attended. Besides serious discussions on the subject, a good program was submitted for the audience.

GILA COUNTY

(Special Correspondence.)—For the International smelting plant, the American Bridge Co. will supply about 6000 tons of steel, and work must be started within 90 days. At the Inspiration, during the past week, two carloads of iron gates for draining the ore-storage bins have been received and are now being put in place of the bins, which will require 140 of the gates. The General Electric Co. has shipped three of the large transformers and they should soon be in Miami. The transformers, which are shipped from Pittsfield, Massachusetts, weigh 5000 lb. each. One of the large Pacific Electric No. 4 air-compressors has been received and unloaded near the main shafts. Bad weather has interfered with construction work and train service. Ore-bins are being erected at the main shafts, and work is to be soon started on the head-frame. The United States Reclamation Service force now has towers of the transmission line erected up to the main east and west shafts and is continuing the work toward Superior.

Miami, January 31.

Assessment and development work is being done on 75 claims of the Troy-Arizona Copper Co., at Troy, south of Globe. An option has been taken on the Rentro group of 40 claims adjoining, the price being \$25,000. Leo Von Rosenberg has 25 men on the various claims.

PINAL COUNTY

At the Ray Consolidated mine, the company is starting a 'safety first' movement. Employees who offer suggestions for lessening risk are given cash prizes; a course of lectures in first aid is provided; pulmotors are installed for emergencies, and a helmet practice is given every month.

YUMA COUNTY

The Swansea Consolidated Gold & Copper Co., operating the Swansea mine and smelter in the northern part of the county, has been pronounced bankrupt. The Farmers' Exchange of Phoenix is the principal creditor.

CALIFORNIA

AMADOR COUNTY

A Spaniard, on being refused work at the Kennedy mine, attacked the foreman, Alex. Ross, with a razor. He was finally overpowered and arrested. Mr. Ross was not seriously hurt. A miner at the Keystone, Amador City, is suing the company for \$5071 for injuries alleged to have been received while attending to a machine-drill.

BUTTE COUNTY

Floods in the Feather river interfered with power for the three dredges of the Oroville Dredging Co., and the gold output was only \$3289 during the week ended January 3.

ELDORADO COUNTY

J. J. Meyers and J. J. Dunn, of Georgetown, have sold a third interest in the Emma group of mines, on the Georgetown divide, to W. T. Russell, of Fresno. The mine will be developed and a 5-stamp mill will be erected at once.

MARIPOSA COUNTY

The Exchequer dam, a concrete structure across the Merced river at Exchequer, was destroyed by the recent floods. It was built about eight years ago by the Exchequer Mining & Power Co., to supply power for several mines near Hornitos. These included the Mount Gaines, Ruth Pierce, and No. 5. In 1911, floods in the river damaged the power-plant, which was only supplying the Mount Gaines at that time. Since then the dam was not used for any purpose, but may have been useful at a later period. Its dimensions were 56 ft. high, 10 ft. thick at the top, 40 ft. at the bottom, and 175 ft. long, and cost \$42,000. It is stated that the Bad Spur dredge, two miles above the dam, has been washed out. The town of Snelling, in Merced county, was partly flooded, but apparently the Yosemite Dredging Co.'s boat was not damaged.

NEVADA COUNTY

Moore's Flat, an abandoned hydraulicking district, is now active through lode mining at the Black Bear, Metropolitan, Nellie V, Golden Shipper, and Bawder's properties. The new 10-stamp mill at the Golden Center of Grass Valley mine has started work.

PLACER COUNTY

A good ore-shoot was recently opened in the east end of the Gold Blossom mine at Ophir. The main shaft is down 480 ft. Ore averaging \$7.50 in free gold and 75c. per ton in concentrate has produced over \$500,000 from this mine. Various causes have prevented its being operated of late years, but J. H. Toler, one of the heirs of the Reed estate, estimates that instead of mining and crushing 43 tons per day at a cost of \$3.75 per ton, a modern plant and methods will reduce the cost to \$1.16 per ton. Ore reserves are estimated at 53,384 tons, worth \$160,019, and a profit of \$79,943. A rearrangement of plant will cost about \$6940. A. C. Lowell, executor of the Reed estate, is interesting Nevada people in the Gold Blossom.

SACRAMENTO COUNTY

The Natomas Consolidated of California reports the result of its gold-dredging operations during December as follows:

| | Gross. | Cost. | Net. |
|----------------------------|-----------|-----------|-----------|
| Natoma field | \$176,974 | \$108,809 | \$ 68,165 |
| Feather River field..... | 49,073 | 24,738 | 24,334 |
| Total | \$226,048 | \$133,547 | \$ 92,500 |
| Crushed rock | 24,087 | 14,571 | 9,515 |
| Water | 2,139 | 1,399 | 740 |
| Miscellaneous income | 25,958 | 7,971 | 17,986 |
| Total | \$278,233 | \$157,490 | \$120,742 |
| Bond interest | | 81,103 | 81,103 |
| Net | \$278,233 | \$238,594 | \$ 39,638 |

SIERRA COUNTY

Work has been resumed at the Independence mine on Wolf creek, below the Plumbago.

COLORADO

For the mining convention to be held on February 19, Denver has been chosen as the meeting place. Twenty-six counties have selected delegates, and about 150 representative mining men will be present.

DOLORES COUNTY

The annual meeting of the Rico-Wellington Mining Co. was held at Provo, Utah, on January 29. The old board of directors was reelected, including Jesse Knight as president. Large shipments of copper and some zinc ore were made in 1913, and at present 20 tons of copper ore is being shipped daily to Salt Lake smelters. The Company's indebtedness is now \$51,000, \$50,000 having been paid off during the term.

GILPIN COUNTY

This county is said to be quite active in spite of the winter, and numerous small claims are being developed. Deeper work is to be done at the Bates mine in Chase gulch. Ore shipments to the Polar and Iron City mills have yielded high gold returns. The Castle Rock is also producing good ore. Shipments from the Pittsburg, in Russell gulch, have yielded 2.16 to 10.54 oz. gold, 3.84 to 10.20 oz. silver, and 4.8 to 19% copper. Development at the Homer, Columbia adit, Cecil lode, and East Notaway is producing satisfactory results.

LAKE COUNTY (LEADVILLE)

A large tonnage of iron ore has been opened in the Henriette mine, Carbonate hill, and shipments are being made. The daily output of iron, lead, and carbonate of zinc ores is 50 tons, but this is to be increased. Development in the Eureka, Lackawanna gulch, is excellent, several hundred feet of ore being opened in the main adit. Lessees at the Little Johnnie, Breece hill, are getting satisfactory results. The Walker adit, at South Evans, is being driven 400 ft., the present rate in hard ground is only 2 ft. per day. This place is at a high altitude, and miners do not stay long. The District mill, lower California gulch, is working full time. A tube-milling oil-flotation process is being tried on the zinc tailing from the Horrigan lease on the Maid of Erin dump. W. H. Campbell, of the Jolly Leasing & Milling Co., states that there should be a change in the smelter charges on iron ores. At present the smelters demand 40% excess in all iron oxide ores. Most of the large iron orebodies in the district contain 3 to 4 oz. silver per ton, and a good deal of silica, and he considers that on a basis of 35% iron there would be a revival in mining at Carbonate and Fryer hills. The Denver City shaft, Yankee hill, is completed, and properly equipped for work. The Mt. Champion mill, Half Moon gulch, is being overhauled. A wide vein has been opened in the Siwatch adit.

OURAY COUNTY

A snowstorm of four days' duration shut down every mine in the county for some time during the last week of January. A flume and transmission wires of the Ames power-plant in San Miguel county were carried away, and power was cut off. A snowslide knocked over a tower of the Atlas tramway, and part of a shed at the Camp Bird, while a considerable amount of minor damage was done.

SAN MIGUEL COUNTY

The Liberty Bell Gold Mining Co. has recently acquired, under lease and bond, some property in the East Mill Creek district, the purchase price being \$10,000. The claims contain gold-bearing veins, and will be prospected by an adit in Cornet Creek basin.

A fierce storm throughout the county did little damage to mining plants, which operated practically the whole time.

The Idaho and Butterfly snowslides carried away power-lines and flumes of the Western Colorado Power Co. The Pandora slide started off with the Bob Tail slide and destroyed two towers of the Tomboy tramway and some cables. These slides rushed to within 300 ft. of the Pandora mill of the Smuggler-Union company, and damaged the Pennsylvania snowsheds and tramway.

TELLER COUNTY (CRIPPLE CREEK)

On No. 11 level of the Gold Coin shaft of the Granite company, the main Granite vein has been opened over 100 ft. so far, and yields rich ore. Dan McCarthy is superintendent. Dividends amounting to \$45,000 and \$26,185, respectively, have

SNOWSLIDE IN CANYON CREEK, OURAY COUNTY.

been paid by the Vindicator and Mary McKinney companies during the last week of January. Lessees at the Isabella mines are satisfied with their conditions, and have published a statement to that effect.

The January gold output of the district was \$1,285,536, from 86,213 tons of ore.

IDAHO

LEMMING COUNTY

A car of rich gold ore has been sent to Salt Lake City from the Allie mine at Gilmore. The vein is 2½ ft. wide, and has been driven on 40 ft., and a raise driven 50 ft. The face gives high assays at present. This is an old silver-lead district, which was almost abandoned except for several prospectors, mainly on account of transport arrangements over 80 miles of road. Three years ago the Pittsburg-Gilmore railroad was constructed to the district, and it became active as a silver-lead ore producer, according to Robert Bell, inspector of mines. The principal work has been done at the Pittsburg-Idaho, Latest Out, and Allie mines. The formation of the district is ancient limestone underlain by Cambrian quartzite. E. C. Ross is manager of the Allie mine.

SHOSHONE COUNTY

The Idora mill, near Sunset, and 1600 ft. below the mine, has resumed work after a temporary shut-down for overhaul. The mill has a capacity of 100 tons per 24 hours, and is connected with the mine by aerial tramway. Concentrate from the mill is hauled 9 miles to Prichard. The mine is looking well, as is also the Tuscumbia, which is under option to the company. M. D. Winder is manager. John Mocine has been appointed manager of the National Copper Mining Co. at Mullan, in place of Charles McKinnis, who is in bad health. At a depth of 400 ft., the cross-cut from the bottom of the Sunset mine shaft has cut the vein. The ore contains lead and zinc. This property is owned by W. A. Clark, of Montana.

On February 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 197, of \$81,750. This makes the total amount of dividends paid \$14,892,750.

There has been further litigation with the Stewart Mining

Co. This was the suit of this Company against Jonathan Bourne, Jr., owner of the Ontario property, for the purpose of getting title to orebodies in the Ontario lode claim, the apex of which was claimed by the Stewart company. It was admitted that the same vein was in the Ontario and Stewart, but in the latter it was faulted. The question for the court to decide was whether the particular fault to which reference was made by parties to the suit constituted a part of the apex of the vein which extended across both the Stewart and Ontario properties, or whether it was only a side or edge of the vein. In his decision, Judge F. S. Dietrich held that it was no part of the apex, and the complaint was dismissed. Both properties contain high-grade ore, and the case was one of the most bitterly contested ever tried in the Coeur d'Alene district.

The American Smelting & Refining Co. has secured control of the Stewart Mining Co. by buying 471,000 shares of the latter's stock. The former Company is also negotiating for another 68,000 shares.

MICHIGAN

HOUGHTON COUNTY

'Rock' shipments from different Calumet mines during the third week in January were as follows: Calumet & Hecla, 8790 tons; Osceola, old mine, 960; South Kearsarge, 1200; North Kearsarge, 920; total for Osceola Consolidated, 3080; Ahmeek, 1480; Mohawk, 1400; Wolverine, 1400; Centennial, 440; and Allouez, 840 tons. At the Ahmeek stamp-mill, two heads are working three shifts, crushing 1700 tons of rock per day. Four heads at the Osceola are crushing 2800 tons. The Mohawk is employing 200 men, and the one-man drill is used exclusively.

The past week has seen a number of additional mines enter the list of the normal producers. Those mines which are now working full handed and producing copper at the rate before the strike are as follows: Superior, Calumet & Hecla, South Kearsarge, Osceola, North Kearsarge, Allouez, Winona, Centennial, and Victoria. The mines which are working normal forces, but which are not producers of copper, are as follows: White Pine, Mayflower, Old Colony, Keweenaw, New Arcadian, New Baltic, Oneco, Hancock Consolidated, Naumkeag, South Lake, North Lake, Indiana, Wyandot, La Salle, Houghton Copper, and St. Louis. The mines which are operating over 75% normal rock output and expect to be in normal condition again within a few weeks are the Baltic, Trimountain, Champion of the Copper Range Consolidated, the Quincy, nearly normal, Ahmeek, and Wolverine. Mohawk is about half of normal in rock production now. The influx of new men to the district continues. Quite a few of the men from the iron mines are coming to the copper district, feeling that the Finnish socialists there will attempt to strike in the near future.

MISSOURI

GREENE COUNTY

Ore has been found at a shallow depth near Springfield, and the district is quite busy. The first shaft has been sunk south of the James river. The Gumbo district is producing ore, which is sent to smelters in Kansas and Illinois.

JASPER COUNTY

The Napoleon mine is producing from 50 to 60 tons of zinc ore per week, and is one of the steadiest properties at Joplin. Last year a large tonnage of zinc and lead ore was produced. Work is carried on at a depth of 150 ft. Drilling at the south part of the lease showed rich ground at 115 to 125 ft., and down to 155 ft. The Napoleon Lead & Zinc Co. is composed of Joplin men. It has a lease on 40 acres of the Nap Perry land. A modern concentrating plant is at work. Of the 4745 tons of zinc ore from the Missouri-Kansas-Oklahoma district during the past week, 1570 tons was from

the Webb City-Carterville sheet-ground area. It also sent out 486 tons of lead ore. Despite low prices, the operators are keeping their mills running. The Galena-Joplin Lead & Zinc Co. has its shaft down 167 ft., but continuous pumping is necessary. Drilling has proved ore under limestone over a good area. W. C. Kramer has secured a lease on the Bonanza land, and will probably start drilling shortly. A new 250-ton mill is being erected by C. C. Yoder and associates. Large pumps are now at work in the Dallas mine. About \$5000 was spent last fall on the Symmes mine plant.

MONTANA

MADISON COUNTY

It is stated that a new company has taken options on 20,000 acres of ground in Ruby valley, near Twin Bridges, for dredging purposes. The options are for the current year only. Prospecting is to start soon, according to H. F. Jackson, representative of the company. Charles F. Helman, of the El Oro Dredging Co. of Oroville, California, has authorized this work to commence. He spent some time in this district last summer and fall.

SILVERBOW COUNTY

Development of the Edith May vein at 2600 ft., in the North Butte, is very promising for further discoveries. At 2000 ft. the Butte-Alex Scott drift has cut the vein. A shoot of 4 to 5% copper was recently cut in the Alex Scott. The property is producing 150 tons of ore per day from the 1900-ft. level. Seventy men are employed. The Butte-Ballaklava shipped 2300 tons of ore in December. The largest ore-shoot is at 1400 ft., where it is 10 ft. wide, against 5 ft. at 1200 ft. and 10 ft. at 800 ft. It is intended to cross-cut from the 1600-ft. station. Last week the miners entered the old 1200-ft. level stopes which were filled with waste, the result of litigation with the Anaconda company. The Butte Ballaklava is working a southeast extension of the North Butte's Jessie vein. Forty-five men are employed. The large flow of water in the Butte & Zenith, six miles west of Butte hill, is now under control, enabling further sinking to be done. Cross-cutting is under way at 2400 ft. in the Tuolumne, and the Jessie vein will be cut about February 23. About 100 tons of ore per day is being mined from a wide shoot at 800 ft. A station is to be cut at 2200 ft. in the Pilot-Butte, and cross-cutting done to cut a 2½-ft. shoot opened at 1800 ft. The Anaconda company's suit against the Pilot-Butte is set for March. The former claims ownership of the South vein, which is alleged to apex in its Emily ground, adjoining the Pilot-Butte.

NEVADA

CHURCHILL COUNTY

It is stated that at the Goldbanks Quicksilver Mines Co.'s property, 35 miles south of Winnemucca, in Pleasant valley, an area of 1000 by 3500 ft. contains cinnabar. A gravity tramway to a 12-ton retort is nearly finished, the furnace now being heated up. The annual meeting of the Nevada Hills Mining Co. was recently held at Reno. Development in the mine at Fairview covered 6243 ft. during the past year. The mill treated 41,919 tons of ore averaging \$13.77 per ton. The net yield was \$510,414. The total expenditure was \$333,448, equal to \$7.95 per ton. The profit was \$176,966. E. A. Julian is general manager.

ELKO COUNTY

The Eureka & Palisade Railroad Co. will construct a line to the mining camp of Bullion. It will be 14 miles long with 2 and 4% grades. There is a large tonnage of profitable ore opened in the various claims.

ESMERALDA COUNTY

The Goldfield Consolidated Mines Co. reports as follows for January: Ore treated, 30,249 tons; gold recovered, \$336,000; operating expenses, \$180,000; and net realization, \$156,000.

NYE COUNTY

Work is to be resumed at the Manhattan Consolidated mine. Water is being taken out by a Cameron pump. The ore from this property is rather refractory, and the California Extraction Co., of Oakland, is experimenting with it. It is said that the Clancy process is being installed at the Associated mill. Good ore has been opened in the Wittenberg-Mushett lease on the Manhattan-Dexter property, at 300 ft. A winze is being sunk to prove the extent of the shoot. A heavy snowstorm visited Manhattan during the last week in January. The West End will pay a dividend of 10c. per share in March, equal to \$178,848. The ore production of Tonopah mines last week was 11,005 tons, valued at \$265,210. A reduction in power and light rates will be effective in the district on March 5. The last quarterly report of the Tonopah Mining Co. shows the following: Gross value of mill products, \$667,747; net earnings, \$358,694; sundry income and dividend (\$54,220) from Tonopah & Goldfield railroad made a total of \$436,678; exploration, \$19,425; and defense of Brown process litigation, \$6592, leaving net income of \$410,660. Dividends of \$250,000 each were paid on October 21, 1913, and January 21, 1914. The Company has organized the Tonopah Placers Co., with a capital of \$1,000,000, to work the dredging areas acquired at Breckenridge, Colorado.

STOREY COUNTY

The 2700-ft. level at the Comstock has been drained, the water being 5 ft. below the station. This is the first time for 30 years that anybody has been to that depth. The drift leading from the station to the Ophir, Mexican, Union, and Sierra Nevada mines is in good condition. Great hopes are held for satisfactory development at 2700 ft. The Starrett pumps have done excellent work in unwatering the area. A. M. Walsh and Leon M. Hall are superintendent and engineer respectively of the United Comstock Pumping Association.

UTAH

SUMMIT COUNTY

Three feet of shipping ore has been opened on the 1550-ft. level of the Silver King Consolidated, at Park City. This makes three faces at this depth where ore is being mined. The Thompson-Quincy mine is being worked as usual in spite of the fire at the Daly West in December. Good ore is being mined.

SALT LAKE COUNTY

The old Yosemite mine at Bingham is again active, and a carload of lead ore has been extracted from the 500-ft. level. The mine, down to 2000 ft., has been drained by the Mascotte adit. A settlement of 37 tons of ore from the City Rocks workings of the Michigan-Utah gave the following result: gold, 65c.; silver, \$25.76; copper, \$1.47; and lead, \$11.22; a total of \$39.10 per ton. Twenty-five men are employed at the property.

WASHINGTON

STEVENS COUNTY

The eighth annual meeting of the United Copper Mining Co. was held at Spokane on January 28. Conrad Wolfe is president. He stated that \$67,000 was spent last year in development, installing electric equipment and enlarging the mill. The lower adit was driven 3700 ft. during 1913. A two-compartment shaft is below the 600-ft. level, and will be sunk 400 ft. farther. Both the adit and shaft should be finished in about 60 days. Generally the mine is in good condition. Statements of ore production and metal output will be published shortly by the Company.

SPOKANE COUNTY

(Special Correspondence.)—The Reata Mining & Milling Co. has been organized by Spokane men, with a capital of \$1,500,000. The mining claims to be developed are near the

Deer Creek mines, 4½ miles northwest of Spokane. About 2000 ft. of work has already been done, and 10,000 tons of ore is ready for shipment. The Providence claim has produced ore worth \$50,000. Silver predominates in the ore, the lowest grade being 10 oz. per ton.

Spokane, January 28.

CANADA

BRITISH COLUMBIA

Shipments of ore from Rossland mines to the Trail smelter for the week ended January 21, also for the year to that date, are as follows: Centre Star, week 3710 tons, year 10,565 tons; Le Roi, week 795, year 3551; Josie (Le Roi No. 2), week 212, year 1330. During the last week 477 tons of ore from the Ben Hur mine, Republic, has passed through Rossland, also 53 tons consigned from the First National Bank at Colville, Washington.

The Second Relief mine at Erie has been sold to Minneapolis people for \$300,000. A. H. Elftman is the principal holder in the new concern, and Litchfield & Hanson were the former owners. Spokane people are interested. The present gold output is between \$10,000 and \$12,000 per month. The British Columbia Copper Co.'s gross earnings in 1913 were \$1,240,000. New holdings, costing \$275,000, were acquired during the past year, and a new concentrating plant will be erected to treat the ores from these properties. The Greenwood smelter can handle the extra product. A bond issue of \$1,000,000 will be used to pay for new works.

ONTARIO

During December the Hudson Bay mill treated 1945 tons of ore averaging 23.6 oz. per ton, with 88.7% recovery, the residue containing 2.8 oz. per ton. The output was 49,721 oz. silver. Thirty feet of ore, worth from 3000 to 4000 oz. per ton and 2 in. wide, has been opened in a branch stringer from the Fleming vein on the 150-ft. level of the Crown Reserve mine. It is consistent in the few feet opened to date. The new development is from the workings driven shortly after the draining of Kerr lake.

During 1913 development at the Wettlaufer Lorrain mine covered 1390 ft., and 982 ft. of diamond-drilling; but results were disappointing. Ore produced yielded 252,864 oz. silver, and the reserves contain only a few thousand ounces. The year's profit was \$38,042, against \$320,249 in 1912.

Thirty-one mines were on the shipping list at Cobalt in 1913, against 27 in 1912. The amount sent out last year was 20,916 tons, and a total of 179,934.31 tons since 1904. During December the Buffalo mill treated 7199 tons of ore averaging 23.27 oz. per ton. Silver recovered was 128,997 oz. A vein has been cut at 280 ft. in the Bailey, and it is figured to be the No. 1 vein, but contains low-grade ore at present.

The Hunton, Horne & Stevenson claims at Kirkland Lake have been acquired by English people, headed by H. Cecil. The Hunton claims include two 40-acre properties about ¾ mile south of the Teck-Hughes. The deal, on a cash and share basis, will amount to about £200,000. English capital is flowing freely into the Kirkland Lake district of late.

It is proposed to amalgamate all the mines at Pearl Lake under one company. These include the McIntyre, which is treating ore, and the Pearl Lake, Jupiter, Plenaurum, Schumacher, and Vipond, which are not being operated. Central equipment will be an advantage to the group. The Foster Leasing Co. is preparing to develop its ground under Glen lake. Nearly half of its 40 acres is situated there.

The International Exploration Co., of Buffalo, has an option for \$160,000 on the Le Blanc property at Keniwisek, near Hurricanaw, and probably this will be completed. On account of proper bridges to the mine, development is temporarily held up. At 46 ft. depth in the Clark claims, 40 in. of quartz assays \$5126, and 30 in. of quartz and schist averages \$32.87 per ton. On the hanging wall is porphyry assay-ing \$3.31 per ton.

Personal

J. C. PYLE is down from Butte.

W. C. RALSTON is in New York City.

E. H. NUTTER has returned from Butte.

E. H. LESLIE is at Bartlesville, Oklahoma.

C. G. TAILLEUR is now at Dayton, Nevada.

EDWARD J. O'CONNELL is in San Francisco.

F. L. SIZER is in San Francisco for a few days.

L. D. RICKETTS was in Salt Lake City this week.

A. CHESTER BEATTY has sailed for the Mediterranean.

F. R. MANN has moved from Globe to Superior, Arizona.

ALBION S. HOWE is expected in San Francisco from Costa Rica.

R. NOBLETT has gone from Bisbee to Pilares de Nacozari, Sonora.

CLEMENT A. FOSTER, of Haileybury, sailed from New York for London.

LESTER A. GREENE is expected from New York and Chicago next Thursday.

D'ARCY WEATHERBE passed through New York last week on his way to Cobalt.

E. T. STANNARD has returned from Chile and is at Binghamton, New York.

W. G. ANDERSON left San Francisco on February 1 to inspect mines in eastern Ontario.

E. C. CONVERSE was married to Miss EDITH M. DUNSHEE in New York on January 30.

WILLIAM J. PRIESTLY, JR., who has been in Latouche, Alaska, is now at Seattle, Washington.

R. S. McCAFFERY has been appointed professor of metallurgy in the University of Wisconsin.

ASKIN NICHOLAS is manager of the Block 14 wolfram mine, at Torrington, New South Wales.

DAVID McCLURE has left San Francisco for a trip through the mining regions of South America.

J. M. KURIE formerly at Philadelphia, is now at 625 I. W. Hellman Bdg., Los Angeles, California.

F. G. COTTELL has been in Butte in connection with the Bureau of Mines work on smelter fume.

HARRY NELSON has resigned as superintendent for the Golden Cycle and will be succeeded by JASPER T. ROBERTSON.

A. G. BURROWS gave a lecture at Porcupine, Ontario, January 29, on the prevailing rock formation in Canada.

P. A. ROBBINS will sail from New York for the Mediterranean, and will spend three months in Europe and northern Africa.

C. M. EYE has just completed a 200-ton mill for the Imperial Reduction Co., near Ogilby, California, where he has charge of the mining property.

M. J. STAFFORD, field engineer with the construction department of the Inspiration Consolidated Copper Co., has resigned and will leave for the Pacific coast.

FORBES RICKARD has been examining mines in the Pioneer district, Nevada. He will visit Pasadena, Catalina, and the Grand Canyon before returning to Denver.

V. A. STOUT has returned from a trip East and will be in San Francisco, where he will be the Pacific coast representative for the New York Engineering Co. and the Hardinge Conical Mill Company.

B. M. SNYDER, of Los Angeles, ALEX. WISE and DONALD CAMERON, of San Francisco, have been assisting R. E. CRANSTON in making an examination of the Zeila mine, at Jackson, California.

DORSEY LYON and R. M. KEENEY, of the U. S. Bureau of Mines, have been detailed to take charge of the metallurgical research station at Salt Lake City established in coöperation with the University of Utah.

Company Reports

CONSOLIDATED MINING & SMELTING COMPANY OF CANADA, LTD.

This Company operates about 15 different mines, and a smelter at Trail, British Columbia, and the report covers the 15 months ended September 30, 1913. R. H. Stewart, general manager, states that the Ottawa at Slocan City, the Silver King at Nelson, the Lucky Thought at Silverton, and some properties on the coast were under development during the period, these being new additions to the existing work. There was 38,741 ft. of 'narrow' work, and 35,288 ft. of diamond-drilling done in the following mines: Centre Star, Le Roi, St. Eugene, Sullivan, Molly Gibson, Silver King, Number One, Highland, Maestro, Libby, Tiger, Richmond Eureka, Ottawa, Lucky Thought, and Silver Dollar. The total development to date in the various properties operated is 418,052 feet.

The Company's mines in Rossland show an encouraging increase in the amount of ore developed, a considerable part of this increase being due to tonnage developed in the Le Roi. Development in depth from the War Eagle mine continues to prove encouraging, a large body of ore, of good grade, having been opened on No. 14 level. A cross-cut from the Centre Star shaft is now being driven to reach this vein at a depth of 300 ft. below this level, and should reach the vein early in 1914. Development in the Le Roi mine has been satisfactory in finding new ore. A dispute regarding the rights to mine certain veins apexing near the north boundary of the Le Roi, where it adjoins the property of the Le Roi No. 2, was settled by an agreement between the two companies, involving an exchange of certain parts of the properties of both companies and the substitution of definite planes for extralateral rights. This agreement should do away with any cause for disputes of this nature with the Le Roi No. 2 company in the future. At Kimberley, development of the Sullivan group has been satisfactory in opening new ore, and the mine should continue to produce for a good many years to come. At Moyie a small tonnage has been shipped from the St. Eugene mine, but no large bodies of new ore have been discovered. The Molly Gibson mine was closed down for about six months last winter, owing to snowslides, which carried away a considerable part of the tramway. The tramway has been repaired and development is proceeding satisfactorily. The cross-cut tunnel mentioned in last year's report has opened considerable new ore, much of it of good grade, and the mine looks better than ever before. Owing to its situation, development is necessarily slow, but the mine should, in time, be a producer of considerable profit. At Sandon there have been no new developments in the Richmond Eureka group, which still continues to produce a small tonnage. At Ainsworth, the Number One mine has been producing ore comparatively steadily, and developing with favorable results. The Highland group is also being developed with fairly satisfactory results. This mine has also commenced producing. The Maestro, Libby, Banker, and Tiger

properties adjoining or close to the Highland and Number One groups, and which the Company has under option, have developed to a small extent and some ore has been produced under lease. Labor troubles prevented full work at the Silver Dollar at Salmo. At Boundary Falls the Number Seven supplied silicious ore for the smelter part of the time. In the Phoenix camp no work was done. Mining activity increased in the Kootenay district, ore shipments to the smelter being 97,823 tons against 47,257 tons in the previous term.

Operations at the smelter for the term were as follows:

| | |
|--------------------------------|-------------|
| Ore from all mines, tons | 407,124 |
| Gold, ounces | 186,017 |
| Silver, ounces | 3,224,408 |
| Lead, pounds | 48,325,252 |
| Copper, pounds | 3,454,814 |
| Gross value | \$8,335,968 |

Covering the period of 1894 to 1913, inclusive, results were:

| | |
|---|--------------|
| Ore smelted, tons | 3,551,051 |
| Gold, ounces | 1,332,929 |
| Silver, ounces | 23,449,031 |
| Lead, pounds | 299,295,896 |
| Copper, pounds | 54,244,797 |
| Gross value | \$60,502,672 |
| Revenue from all sources in 1912-13..... | \$ 9,148,714 |
| Ore, lead, and bullion purchased..... | 3,151,325 |
| Development | 598,240 |
| Mining, smelting, and general expenses..... | 3,110,794 |
| Freight on Company's ore | 71,046 |
| Ore and smelter products | 868,112 |
| Development, written off | 146,019 |
| Depreciation | 193,256 |
| Directors and sundries | 11,554 |
| Profit | 998,367 |
| Dividends (3, equal to 8%)..... | 464,352 |
| Credit of profit and loss..... | 1,717,650 |

At the Le Roi experimental mill, tests have been carried

TRAIL SMELTER, BRITISH COLUMBIA.

out on concentration. The head-frame at the War Eagle was burned, but did not stop ore supplies. At Ainsworth was installed an aerial tramway 9000 ft. long, from Number One mine to the lake. Several improvements were made at the Highland and Kimberley mines. At the Trail smelter one of the copper furnaces was lengthened to 35 ft., preparation was made for installing a new lead furnace, and for rebuilding the lead furnaces.

New York Metal Market Review

All of the important metals finished 1913 with considerable activity. January opened quiet, but with a better feeling, which grew in force as the month progressed. Copper was affected only temporarily by the unfavorable statement for December, issued January 8 by the Copper Producers' Association, and toward the third quarter of the month electrolytic advanced under a good demand. Lake was nominal throughout January. In spelter, there was an excellent buying movement, following greater activity at the sheet mills. Lead quotations were between 4.10 and 4.15c. per pound, New York, from January 1 to 28, and the heaviest buying was in the third quarter of the month. Antimony was uninteresting, although there was an effort to force sales. In tin, there was some heavy purchasing, under which prices advanced. Quotations for aluminum showed no variations in January, and on the whole the metal was quiet. The feeling in all lines is that a betterment in business conditions is on the way, but that it will come slowly.

COPPER

The review of December covered the market to December 23, on which date there was no indication of impending activity, and it was thought that 1913 would finish with the dullness that had so long prevailed. On December 26, 27, and 28, however, buying was heavy, and millions of pounds were sold, about 75% being for export, according to report. One result was that electrolytic, which had been quoted at 14.37½c. cash prior to the movement, went to 14.87½c. on January 2. Lake was nominal on that day at 15.12½c. cash. The Waterbury average for December was 15c. Total exports in December were 30,503 tons. Total exports for 1913 were 382,660 tons. Immediately after the subsidence of buying in the last days of 1913, dullness set in again, and while prices held for the first week of 1914, they were nominal. On January 8 the market suffered a hard blow when the Copper Producers' statement for December appeared. It was a great disappointment to the trade, inasmuch as while it was not expected to be favorable, no one figured that domestic deliveries would be as low as 21,938,570 lb., or that surplus stock would rise to 91,438,867 lb., an increase of 43,509,438 lb., the largest increase in the history of the records. In the face of the statistical showing and the lack of demand, electrolytic dropped to 14c. cash, New York, by the middle of the month, with Lake nominal at 14.50c. The last prior sale of Lake was at 15.12½c., and then it was to be had only from one or two producers. At around 14c. some activity started in electrolytic with Europe again figuring in the bulk of sales, though domestic consumers took more than they had for some weeks previously. Prices advanced under the demand, and by January 21 electrolytic was quoted at 14.37½c. cash and Lake was nominal at 14.75c. cash. With the better buying referred to came an improved feeling which survived the activity and lasted to the end of January. It was justified, as in the third week of the month came another buying movement which, while not heavy, was fair, with Europe again the largest purchaser. Quotations advanced until on January 28 electrolytic stood at 14.50c. cash, New York, with Lake at 15c., although in the latter there had been little or no action. Few resale or speculative lots of electrolytic were in evidence at this time, holders of such metal evidently believing that they could obtain full prices by not pressing sales, despite the dullness then prevailing. The exports up to and including January 30 were heavy, amounting to 33,690 tons. The quotation on January 30 for electrolytic was 14.62½c. cash, delivered, New York.

SPELTER

This metal took on added strength under the stimulus

of better inquiry and improved buying at the very end of 1913, as did copper, and quotations advanced to 5.35c. New York and 5.20c. St. Louis, on December 29. These new prices caused the base price of sheet zinc in carload lots to be advanced 25c. per 100 lb., to \$7.50 per 100 lb., less 8% discount, f.o.b. cars Peru, Illinois. Later in the month this advance was lost. In most of January there was little doing, and by the end of the second week quotations had dropped to 5.25c. New York and 5.10c. St. Louis. After January 15, however, the market became firm again, and with the reports of increased production of sheets there came an excellent demand with buying good on January 22, 23, and 24. Prices moved upward again, and by January 27 the New York quotation was back to 5.35c., although buying had eased off. The quotation on January 30 was 5.40c. New York.

LEAD

In lead, also, there was an improvement in the final days of 1913, the American Smelting & Refining Co., on December 29, advancing its price 5 points to 4.15c. New York. At the low price which had been prevailing, the big interest had been taking most of the business and probably more than it wanted to at these figures. Meanwhile the western quotation eased off until January 9, when the New York price was again made 4.10c. New York by the American Smelting & Refining Co. This drop was a surprise to the New York trade, as it was generally believed that an advance was in order. The St. Louis price on January 15 was 3.97½c. About this time good inquiry appeared, some of it from abroad, although the New York price, 4.10c., was not low enough to permit of profitable sales for export. Metal could have been shipped at 3.95c. f.o.b. New York, but the price at this port, as noted, was 15 points higher. The margin was rather close, but it excited no uneasiness for the reason that producers have shown little desire to export their metal. Between January 21 and 28, the market was exceedingly active at 4.10c. New York level, and under the demand the St. Louis price crept up to 4.02½c., and all the indications were that the eastern price would advance accordingly. In the good buying referred to, both consumers and dealers took metal. Quotations in London had sagged toward the end of the month, but this did not disturb the American market. The quotations on January 30 were 4.10c. New York and 4.02½c. St. Louis, with independent producers asking a few points more.

ANTIMONY

The market was unsatisfactory throughout January, as it had been for several months. At the end of 1913 the situation was easier, because of a disposition to give concessions to induce buying. Little success was met in the endeavor. January opened with Hallett's at 7 to 7.25c., Cookson's at 7.45 to 7.60c., and Chinese and Hungarian grades at 6 to 6.50c. On January 30, Hallett's was practically unchanged, but Cookson's had dropped to 7.25 to 7.35c. Other brands were still 6 to 6.50c. Government statistics showed that importations had fallen off heavily in the latter part of 1913, but there was a large stock on hand, and conditions indicated a desire to liquidate the accumulated metal. Much of this stock had been landed prior to the new tariff becoming operative.

The annual report of the Mary McKinney Mining Co. shows the following:

| | |
|---------------------|-----------|
| Development, feet | 2,901 |
| Stoping, cubic feet | 58,277 |
| Company's ore sales | \$293,434 |
| Lessees' ore sales | 52,662 |
| Total earnings | 348,092 |
| Total expenses | 235,902 |
| Net profit | 112,190 |
| Dividends | 104,749 |

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, February 5.

| | | |
|--|--------|---------|
| Antimony | 9 | 93.4c |
| Electrolytic copper | 15 1/2 | 153.4c |
| Pig lead | 4.40 | 5.35 |
| Quicksilver (flask) | | \$39.00 |
| Tin | 11 | 42 1/2c |
| Spelter | 6 1/2 | 64c |
| Zinc dust, 100 kg. zinc-lined cases, 7 1/2 to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York.)

New York, February 4.—The past week has shown a steady increase in copper prices from 14.50 to 14.70c. per lb. Present demand is strong, and prices are advancing. The Copper Producers' report is due on February 9, and an increase of between 1,000,000 and 20,000,000 lb. in stocks is expected. January copper returns are as follows: Anaconda, 24,400,000 lb.; Chino, 6,131,840 lb.; and Copper Range subsidiaries, 3,276,000 pounds. German consumers have bought copper at 14.70 cents. Lead and spelter are firm at 4.15 and 5.25c. respectively. In London, tin is strong at f187 10s. for spot. Large speculation in various stocks is still being indulged in in London, and markets are buoyant.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | Average week ending. |
|---------------|----------------------|

| June | 59.03 | Dec. | 57.73 |

Throughout the week ended January 15, according to Pixley and Abell, some Indian covering has been going on, and, in addition, about f100,000 has been bought for this week's steamer. As some shipments have also gone to the Continent, stocks in London are still about f1,800,000. The China banks have been quiet, but gave some support to the market earlier in the week. In view of the Chinese New Year, which commences on January 26 and lasts until the 29th, inclusive, it is doubtful whether China can prove a great source of strength to this market at present. In spite of this, however, Bombay will probably want more silver for the settlement steamer, leaving next week, and there are still some bears to be covered. As American sales are falling off, possibly owing to large purchases for the United States Mint, and also to the Mexican troubles, and as stocks in London are largely under control, the general appearance is not unhealthy.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

| June | 14.71 | Dec. | 14.25 |

The copper market strengthened considerably last week, though without large sales. On Monday orders were few and on Tuesday some dealers did a good business, while others did not. On Wednesday, January 28, word came that the London agencies were asking the equivalent of 14 1/4c. for 30 days' copper and doing fair business. The same price was asked in New York the next day, but sales were small and also on January 30. Some Calumet & Hecla and Quincy copper sold at 15c. Exports of copper for the week ended January 29 totaled 8473 tons; since January 1, 33,690 tons; same period last year, 23,048 tons.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

| Date. | Average week ending |

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Jan. 22 | Jan. 29 | Feb. 5 |
|-------------|---------|---------|--------|
| Jan. 8 | 39.50 | 39.00 | 39.00 |
| 15 | 39.50 | 39.00 | 39.00 |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

ALUMINUM

Throughout January the market for aluminum was dull but steady at 18.50 to 19c. for both domestic and foreign, prompt delivery metal, 98 to 99% pure. This range of price applies to large purchases, smaller quantities running proportionately higher. Government statistics issued January 20 show that the imports of aluminum in November 1913 were only 1,055,869 lb., whereas in the same month of 1912 they were 3,743,210 lb. In the early months of 1913 the imports were large, and the total for the 11 months ending November 1913 were 21,820,972 lb., as against 18,956,468 lb. in the first 11 months of 1912. Near the close of the month 18.37 1/2c. was bid for a large quantity but was refused.

Tin in January

There was fair buying at the latter end of 1913, a final flurry which ceased when prices went up. December deliveries totaled 3100 tons. The total deliveries for 1913 were 43,900 tons, a decrease of 5600 tons compared with those of 1912. The total visible supply December 31, 1913, was 13,893 tons, which was 2916 tons above that of December 31, 1912. In stocks and landing, December 31, 1913, was 2199 tons. In the first week of 1914 there was only a moderate business, with the price on January 7 around 36.60c. In the next week, January 8 to 14, quotations hovered between 36 and 37c., but business was lacking. In the week of January 15 to 21 the market showed more life, both inquiries and sales becoming more frequent and with dealers doing some of the buying. Between January 15 and 21, quotations reached and exceeded 37c., the price on the latter date being \$37.85c. The price on January 30 was 40c. The arrivals in January were 3235 tons.

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f. o. b. San Francisco. Buying prices marked *.

A New Classifying Jig

A new machine is now being put on the market known as the 'Shields & Thielman combined classifier, jig, and slime separator.' It was originally developed at the Quincy mine, Hubbell, Michigan, by James W. Shields and in that mill has replaced all trommel screens, bull jigs, middling jigs, Hancock jigs, Woodbury jigs, and Richards pulsating classifiers. The exclusive manufacture of this machine is now in the hands of Chalmers & Williams and many separators are being placed in mills as a result of their efforts. The following information is supplied by that firm:

The separator is really a 16-compartment jig and has 4 sections, each being divided into 4 compartments and each compartment having its own independent plunger. Each of these 16 plungers, which are made of bronze and work in cast iron cylinders, can be adjusted separately so as to give the amount of throw best suited to the work. The compartments in which the plungers work are bored like cylinders, the lower ends of each being opened to the compartment under its respective screen. There are vertical screens be-

tween each compartment, which classify the material as it travels from the feed to the tail end of the machine. It will classify and jig a mixed feed direct from the crushers from a size of 1 $\frac{1}{4}$ in. down to as fine as 100 mesh. The slime passes out from the tailing end of the machine, while classified concentrate, middling, and tailing are delivered from each section separately.

The machine occupies a floor space of 12 by 4 ft., a head room of less than 7 ft., and is handling successfully from 450 to 500 tons of ore for 24 hours. It will handle any ore that can be treated on jigs and requires but 4 hp. to operate. Above the bed is a system of chats, which are adjustable, permitting the removal of concentrate, middling, and tailing above the screen as well as the hutch product below.

Commercial Paragraphs

DREDGING is becoming more popular in the Malay States tinfields. Following the success of Malayan Tin Dredging, Ltd., and the Kamunting company, the Ipoh Tin Dredging, Ltd., has ordered a bucket dredge. It will be a Werf Conrad boat and delivery was promised in six months, the price being £24,000.

UNITED STATES BUREAU OF MINES rescue cars carrying the helmet types of mine-rescue apparatus have just been re-equipped with the mouthpieces and corrugated tubes that are used with the Fleuss apparatus. The same change has been made on the Illinois rescue cars. This is an interesting confirmation of those who have maintained that the helmet itself was unnecessary and expensive and even, because of possible leakage around the face, a source of danger.

SYMONS BROS. Co. are manufacturing a pulsating screen which makes a radically new application of certain old principles. The three things essential to a screen are: (1) to keep the openings clean; (2) that the travel of the material over all the screen surface should be at the right pace; and (3) a simple, strong construction. The Symons pulsating screen is a horizontal, step screen, the body being carried on springs. As the screen is forced downward and backward the springs are compressed. They are then suddenly released, with the effect that the screen springs upward and forward, feeding the material evenly over the surface and giving a jig-like motion. The stone particles are partly thrown out of the screen openings and partly pass through. The travel is in a series of short, rapid jumps. The body is supported upon two shafts by hanger arms, and the whole construction is designed for rigidity and strength.

The Plumb pneumatic jig, now being introduced by the AMERICAN ZINC ORE SEPARATING Co., is the invention of A. M. Plumb, who has been engaged in treatment of complex zinc ores for twenty years. He was one of the engineers who helped develop the old Blake-Morsher machine into the present successful electrostatic separator. The Plumb jig uses the same principle as the Richards; that is, the introduction of a pulsating motion into a current, in this case air instead of water, by means of a rotating valve. This causes the crushed rock and mineral to dance on the screen as in an ordinary jig. The result is the building up of a bed of the heavy mineral on the screen and by suitable arrangement of outlets this automatically discharges as the weight of the column on the screen becomes more than that in the discharge. The machine is simple and compact and is reported to make remarkably clean concentrates.

THE RAILWAY operated by the El Oro Mining & Railway Co., Mexico, earned \$524,178 during the past fiscal year. The cost of operation was \$288,211, and the profit was \$235,967.

GOLD PRODUCTION in India in 1913 totaled 589,311 oz., averaging about \$18.50 per oz., against 584,838 oz. in 1912.

AUSTRALIA is not content with the building of one trancontinental railroad, that now under construction from South Australia to the west coast, but has also undertaken a main north-south line. A piece of road 54 miles long in the Northern Territory, and ultimately to form a part of this second main line, has just been authorized. The total distance to be traversed is 1063 miles.

FREE COINAGE of silver has recently found an exponent in the person of Sr. Victoriano Huerta, who is trying to recoup the coin shortage which resulted from the heavy exportation of silver coin previous to that being forbidden by the Mexican government. Undoubtedly the results of this policy will be watched with great interest by its erstwhile champion of "cross of gold and crown of thorns" fame.

DIRECTORS of corporations are held to have large power in an opinion recently delivered by Mr. Justice Cardozo of the New York Supreme Court, in which he is quoted as saying: "The business of a corporation is to be conducted by its directors. They are not required to follow the recommendations of stockholders. Still less are they required—if, indeed, they are permitted to abdicate their functions and surrender to a stockholders' committee the right to control their discretion." This raises the question as to just why there are stockholders. It is, unfortunately enough, common for minor stockholders to be ignored by those holding a major interest, but that directors "are not required to follow the recommendations of stockholders" appeals to us as novel.

MINOR STOCKHOLDERS in the Mining Science Publishing Company received short shrift at the final meeting of that corporation at Denver in December. Our Colorado contemporary had fallen on evil days in a business way, and, as debts were proving embarrassing and collections slow, the principal stockholders arranged to turn the property over to the Union Printing Company. Motions calling for a statement of receipts and disbursements and for the appointment of a committee to audit the books and accounts were promptly voted down and the original plan as promptly put through. We do not remember to have seen a more cynical exhibition of the art of freezing out minor stockholders, and now that it has been ac-

complished, *Mining Science* appears as usual, with no signs of being bankrupt. We cannot believe that the engineers whose names appear on the title page have read the minutes of the stockholders' meeting of December 17, and we suggest to our friends, Messrs. D. W. Brunton, J. W. Finch, Howland Bancroft, Cassius A. Fisher, Victor G. Hills, Thomas B. Stearns, and the others who are listed as members of the 'Editorial Counsel,' consideration of the philosophic comment of Old Daddy Do Funny's angle worm:

"I could stand de hook," says de angleworm,
 "An' a lily-brook wouldn't make me squirm,
 But I can't help wrigglin' ag'in' my fate—
 It breaks me all up to be used for bait."

Fostering Foreign Trade

From time to time we have frequently called attention to the many obvious ways in which the Department of Commerce and other governmental agencies could render more effective service in developing and building up the foreign trade of this country. It is with peculiar pleasure, therefore, that we record that one of the necessary steps has already been taken and another bids fair to quickly follow. The new banking act has been much discussed, but too little attention has been given to one of its most important features: the section permitting national banks to establish branches abroad. In the past, national banks have not been permitted to establish branch banks in other cities, apparently on the theory that such an arrangement would permit one community to draw away money from another.

An equally important matter is the need for commercial attachés to embassies for the purpose of scientifically studying the possibilities of foreign trade; a need to which we have frequently called attention. Even the smaller European countries have their attachés in every important commercial field, and, in a letter to the *London Times*, an Englishman not long ago urged the necessity of the British government increasing its commercial staff in China to three attachés and twenty subagents in order to keep its work upon a par with that which the effective German organization is now doing. We have not even one commercial agent in China, and yet some of us wonder why our trade there does not increase faster. A bill has recently been introduced into Congress with the support of Mr. William C. Redfield, Secretary of Commerce, providing for the appointment of fourteen commercial attachés, at a salary of \$4000 to \$5000 per year, to posts in the leading commercial nations. This somewhat tardy recognition of an obvious need deserves the instant and hearty support of everyone interested in foreign commerce and also the backing of those who have no foreign interests, for whatever benefits some of our people is not without its effect on the nation as a whole.

Whether any real benefit will be derived from the work of the attachés will entirely depend upon the considerations which govern their appointment.

Salted Placers of Santo Domingo

By J. W. LEDOUX

At frequent intervals during the past ten or more years there have been brought to the United States propositions for the investment in mines in Santo Domingo. The most lurid prospectuses and statements have been presented, representing that fabulous wealth exists principally in the shape of gold quartz veins and placer deposits. These placer deposits have been generally represented to exist in the red soils of the plains, or highlands, between the rivers at the foothills of the mountain ranges.

Many people of means have been induced to invest in leases and concessions, and several mining engineers of experience have been sent down to make investigations and verify the claims of the promoters. In nearly all cases the engineers have come back with more or less favorable reports, and findings averaging \$10 to \$20 per yard have been reported for areas covering thousands of acres. The accounts of these deposits have not always referred to the same locality, but the most advertised region is that in the vicinity and within 20 to 50 miles of the City of Santo Domingo, covering the mountainous region at the headwaters of the Nigua, Jaina, Isabella, and Ozama rivers.

There are no roads in this vicinity, simply mountain trails, and no mining operation on any considerable scale has as yet been started, but stories are told of fabulous wealth in gold extracted by the Spaniards several hundred years ago, and there are many evidences of their old workings, especially on the highlands; but reliable tests have been made at and in the vicinity of these workings, none of which has shown commercial gravel to exist. The fact that during all this time no one has had the faith or enterprise to install sufficient plant to mine on a large scale is fair evidence that nothing of material value has as yet been discovered. I was informed of a large stock flotation scheme, known as the 'A. L. Brown' episode, some years ago, when the most gigantic deception was practised by a Santo Domingo resident on many American investors, and the fraud was afterward discovered.

Another story that is current states that this same resident of Santo Domingo sent a sample of red soil to a firm in the United States with an inquiry as to its suitability for paint. This firm had their chemist analyze the soil, and he reported that it contained considerable gold. The firm then wrote to the man in Santo Domingo for a larger sample and inquired whether he had much of this same kind of soil. A second large sample was sent, and tested in the same way, and found to contain even more gold than the first. The firm then started negotiations with the Santo Domingo man which resulted in an option or agreement to purchase for a large sum of money and the payment down of a large sum. They then started operations and soon discovered that there was no gold

of any account where the material came from. They then sued the Santo Domingo man for fraud in the Dominican courts and were non-suited on the ground that he did not pretend that there was gold in the soil, and that his negotiations were carried on entirely on account of the possible prospective paint value.

About a year ago this Santo Domingo man and several associates interested some Philadelphia people in property along the Jaina river, and these people sent a reputable mining engineer down to examine the property. The engineer, on account of his general knowledge of the country and previous experience in similar formations, prior to making the examination, was extremely skeptical as to the presence of any gold gravel of value, and so advised his principals. Nevertheless, he made the investigation and found that several of the streams emptying into the Jaina river contained gold, for there were many natives, especially women, who made a business of panning gold on these streams. His investigations showed that the river bed was narrow and steep for miles, and suddenly widened out into a large deposit of gravel, which would afford excellent ground for dredging, providing it contained gold, and as it was close below the mouths of these gold-bearing streams, he thought it was worth a trial. He, therefore, obtained a drill capable of testing the ground, and when he commenced work had only 15 days to make the test, when it was necessary to make a considerable payment for the concession. He sank some half dozen holes, as well distributed as possible, to test the ground and found gravel averaging over 50c. per cubic yard for an average depth of about 30 ft., and on these findings took the chance of wiring his people to make the first payment. Soon afterward he started other drillings to test this gravel deposit completely, and eventually sank some 100 holes, 500 to 1000 ft. apart. The average value of the gravel amounted to over 30c. per yard. During this operation it was found necessary to purchase other concessions on account of conflicting claims and so as to secure entire right to the use of the river. The payments necessary to be made on these concessions covered a period of over a year, and, in all, these people paid some \$130,000 for the properties and spent about \$60,000 in tests and borings.

In order to make doubly sure of these results before installing the dredge, corroborative tests were made with test pits and independent drillings. This revealed the fact that the findings of the original tests were erroneous, and finally one of the workmen confessed that the native foreman on the work, the women panners, and others had persistently salted the samples from the beginning, the final outcome being a total loss of a large sum.

The man notorious in the paint episode induced some Philadelphia people to investigate a concession known as the Buena Ventura, which adjoins the Jaina river, and told them the gravel would average at least \$2 per yard for thousands of acres. One of these men

happened to have some 15 years' prospecting experience in South America, Nicaragua, and the western part of the United States, and was familiar with sluicing, panning, and all operations connected with placer gold. He was engaged to make the investigation in June 1913. During his first week on the property he was very favorably impressed, as he obtained results averaging some \$10 or more per cubic yard. Then he did some drilling and digging independently when the natives were not around, and was surprised to find that he got no gold. After this he tested some of the original drillings and found no gold, and after two or three weeks' work was convinced that his original work had been salted in every case. This he reported to his people in the United States, and as the alleged owner of the concession was in Philadelphia at the time, he was asked to pay back all the money that they had spent. On his refusal, he was arrested and the case brought before the Grand Jury, and before letting it go too far, he settled the case by paying the people what they demanded.

In the latter part of July 1913, some Philadelphia people, who formed a corporation known as the Jaina Mining & Improvement Co., employed me to go to Santo Domingo and investigate a concession known as the Pedro Bran, which adjoins the Buena Ventura, and is alleged to be owned by the same man. He had leased to this Company the portion of this concession adjoining the Jaina river on the basis of 25% royalty and a payment down of \$4000. One of the members of this Company had previously been to Santo Domingo in January 1913 and was thoroughly acquainted with the owner of the concession, and had made numerous borings and tests and found extremely high gold content, amounting to an average of \$30 or more per cubic yard. He had later reported this to his son, a man of over forty, who, being very skeptical, went down with his father to corroborate the tests of the former. The second tests, made some time in May, were even more favorable than the first ones. I went down in August in company with both of these men and another young man, a son of one of the members of the new company. During the first four days augur borings were made near the places which had been previously tested by this man and his son. The highest value was \$43.20 per cubic yard, and the average of the first ten holes, which covered a distance of about three miles, was over \$12 per cubic yard. I then continued the investigation alone with native employees, and sank some 80 holes, covering a territory four miles long and two miles wide, the average being over \$11 per cubic yard.

On account of a revolution being started at this time, and some other positive reasons which cannot be stated here, it was necessary to wind up the work before the investigation was satisfactorily completed, and for this reason I spent the last two days in making borings and panning the material without the aid of anyone. Although I had up to this time heard none

of the stories above outlined, I was extremely suspicious of the results, and these suspicions were confirmed when I failed to find any gold in my own panning. I then went to the United States and made a complete report of the matter, and also stated my suspicions, and recommended that I be sent down again with one or more reliable men. My suggestions were adopted by the Company. I therefore took one reliable man and went down, thoroughly prepared to test the ground by means of an improved 'Long Tom,' which required a hose stream and the use of rakes to disintegrate the clay and concentrate the gravel, which was constantly passed through a sluice containing riffles. Two pumps were sent down, one to work by hand, requiring four men; the other to work by gasoline. The gasoline pump had a capacity of 125 gal. per minute against 25 ft. head, and the other was a diaphragm pressure pump, good for 75 gal. per minute under any pressure up to 50 lb. It was decided to make the preliminary tests by the hand pump.

In one of the original tests there were seven augur holes drilled to an average depth of about 6 ft. and covering a space of about 50 ft. in length. These showed over \$20 per cubic yard. The reason so many shallow holes were sunk here was that rock or boulders were encountered, and an attempt was being made to sink a deep hole. To verify these findings, a trench 3 ft. wide, 6 ft. deep, and covering the entire ground where the holes were dug, was excavated, and the material was hauled by means of an ox-cart to the 'Long Tom,' which was placed on a small stream about half a mile distant. Not a color of gold was found. In order to be certain that the apparatus was not losing gold, a given amount of fine lead filings was mixed with the material, and in every case it was recovered in the pan. We then sank test-pits around other holes and panned average samples of the material, and in this way re-tested 13 more of the original holes which had given the highest results. These were scattered over an area of three miles long and two miles wide. Not a particle of gold was found in any one of them, and the pans in the majority of cases contained from four to twelve particles of lead, purposely placed there to verify the panning, and which was in all cases recovered.

I then went to Santo Domingo and confronted the owner of the concession with the statement that his employees had previously salted nearly all the holes, and advised him to pay back to the Philadelphia company all the money it had cost them. This man denied having anything to do with any salting operation and stated that while he was willing to pay back all the money, that he was not financially able to do so. I then took the matter up with the American Minister and gave him a complete report of the facts.

During my first visit in August, in looking over the documents and papers concerning the concession, I found that this man had, both as individual and as president of the Barrero Mining Co., which was alleged to be the assignee owner of the Pedro Bran concession,

made a lease to some Philadelphia men of this same property. The lease provided that substantial machinery capable of handling 1000 yd. per day should be installed as soon as possible, and that preliminary work must be begun prior to September 13, 1913. Therefore, the lease to the Jaina Mining & Improvement Co., and the money paid on account of same, was a fraudulent transaction while this previous lease was in existence. One of the parties to the lease came to Santo Domingo and began preliminary work about September 3, 1913, and while it was claimed that he got on the wrong property, he and his men swore differently. During their operation, however, five of the employees died suddenly with what was alleged to be fever, but it was afterward rumored around the city that they had been poisoned. While fever does exist at times among the natives, the fact of so many people dying suddenly within a couple of weeks in the same locality was remarkable.

The alleged owner of the Pedro Bran concession, the Bueno Ventura concession, and the president of the Barrero Mining Co. was Ely Dorsey, a man who was originally supposed to come from Virginia and who has been living in Santo Domingo for many years. He was also the owner or part owner of nearly all the other concessions in this neighborhood. Intimately associated with him is one Pardo, the Santo Domingo agent of the Clyde Line, and I am informed that the following parties were more or less interested in the concessions known as the Ozama, Cuallo, Jaina, and Santa Rosa: Ely Dorsey, Pardo, Gonzales, Vincante Francischini, Rodrigues, Leonti Vasquez, and others. I only know of my personal knowledge that my samples were salted by employees of Ely Dorsey.

The purpose of this recital is to warn prospective investors from undertakings of this character. They would be a good deal safer in playing a 'three-card Monte' or 'shell game' against an expert swindler.

It might be interesting to state the probable manner in which this salting was done. From the best of my judgment, due to inspection and statements made by some of the Dominicans, the natives engaged in the work carried in their pockets small pellets of clay, prepared fresh each day, and about the size of homeopathic pills. Each one of these contained a few particles of gold. At convenient times these were secreted between the fingers and released among the dirt which was to be panned. The women who did the panning and who also performed their part in the salting when necessary, carried the particles of gold in the pocket which contained their smoking pipe, and as they were incessant smokers and always smoked before panning, took out a few particles of gold with their pipe and readily dropped it into the pan without discovery. As this operation has been going on for a good many years, there is no doubt that they are as skillful and dexterous as a magician or sleight-of-hand performer. A man who is not informed in advance of all these possibilities has very little chance of discovering the salting.

Messina Copper Mine, Northern Transvaal

By OWEN LETCHER

Interest in the cupriferous deposits of the Union of South Africa has hitherto centred mainly in the mines of Namaqualand, in the Cape Colony. During the last two or three years, however, the Messina mine, situated in the extreme northern part of the Transvaal, a mile or two to the south of the Limpopo river (Transvaal-Rhodesian border) has attracted much attention by reason of the ambitious development policy initiated, the substantial shipments of concentrated ore made, and the plans of the management to increase production. This property is in a sound position to-day, and that it is about to take a position of greater importance in the list of productive mines of the Union than it has hitherto held seems undeniable. Substantial reserves of ore have been blocked out, a new 250-ton concentrator has just been completed, and a short time ago smelting operations—the first to be conducted

roads; water was scarce, traveling and transport was difficult owing to dense bush; and the nearest base for stores and supplies, by the only available route, was the town of Pietersburg, the northern terminus of the Central South African Railways, about 140 miles south of the copper district. Owing to the enterprise of the Messina company these conditions have been vastly altered.

Character of the Ore

The principal rocks of the district are granite, gneiss, and schists, with masses of quartz and hornblende. The copper-bearing belt or zone is characterized by lines of fissuring. The chief discoveries of copper-bearing lodes so far are confined to the lines of old workings that generally follow the shear-zones which have been traced at Messina, running about north and south, for over 15 miles. The copper occurs as carbonates and sulphides, chiefly redruthite, bornite, chalcopyrite, and malachite.

The lodes run about parallel. The distribution of the ore is somewhat irregular, rich shoots occurring along the strike extending over 150 ft. in length, with intervening zones of poor or barren ground. The width of the orebodies varies in size from a few inches of compact ore up to 30 ft. or more, with rich masses of almost solid copper minerals that have been found to extend continuously in depth, from level to level, without showing any appreciable decrease in width or value.

Two main shafts, and a number of small pits, have been sunk on the property. In the old main 3-compartment shaft the principal ore-shoot, known as the Bonanza, was intersected at a depth of 764 ft., and the shaft continued in solid ore to the bottom. The 900-ft. level has recently been opened, where the ore is found to be of good value. Three lodes are now being worked. The north lode, which has proved to be the best ore-carrier, has been developed by continuous drifts along the strike for over 1500 ft. A new three-compartment shaft is down to the 700-ft. level and will be sunk to a depth of 1000 ft. A new hoist, with a capacity for at least 2000 ft., is being installed.

Preliminary exploitation of the lenticular cupriferous deposits of Messina commenced shortly after the end of the Boer war, and so satisfactory were the results that early in 1905 a company was formed, with a capital of £250,000, to acquire and work the Berkenrode, Vogelzang, Tempelhoff, and Maryland 'farms.' At first, ore was roughly sorted by hand; but in 1909 a concentration plant commenced operations, and there was a consequent substantial increase in output. From the end of June, 1906, and up to the middle of last year, the Messina company mined 76,135 tons of ore

NEW 250-TON CONCENTRATOR UNDER CONSTRUCTION.

on anything approaching a large scale in the Transvaal—were commenced at the mine. The Messina copper deposits lie in the centre of a huge granite area which extends beyond the Limpopo river into Southern Rhodesia. In this formation are numerous ancient workings, which indicate that this district was at one time the scene of an active industry in the mining and smelting of copper ores by native workers. The existence of these ancient workings scattered throughout South Africa has been known for many years. Those in the northern Transvaal were discovered by early hunters and prospectors; but it was not until 1902, after the termination of the Boer war, that active prospecting operations were attempted. At that time the region in the neighborhood of the Limpopo river was looked upon as a death-trap to white men, owing to malarial fever being prevalent during the rainy season; the country was infested with wild animals, and had but few native inhabitants. There were no

and produced 10,861 tons of concentrate averaging 52.7% copper. Productive work has of recent months been restricted, and energies concentrated on development and construction of additional plants in anticipation of the extension of the railway from Pietersburg to the Limpopo. The line has now been extended almost to the mine, and the Company is taking advantage of the facilities provided by the administration and the nearness of the railroad to the property.

Shipments and Ore Treatments

The shipment for last June, 462½ tons of concentrate, averaging about 40% copper, constitutes a record for the mine, and it should be noted that this result was obtained with an old mill of comparatively small capacity. A word regarding the grade of concentrate produced may here be in place. An examination of shipments during different periods reveals the fact that there has been a steady diminution in metallic contents per ton since 1906. Thus in that year the average assay of the 280 tons of concentrate produced was 66% copper. In the next year, from July, 1906, to the end of June 1907, the average was 60.66. The next year the copper had fallen to 58.3%, and in the next period it was 52.3%. This decline in grade has continued, and is, of course, due to ability to work ores of lower grade as the years have gone by and the mine and its equipment have become established. In the earlier days of the property the highest grade ore was hand-picked and shipped to Pietersburg in donkey-wagons. Lower grade ore, which can today be worked at a profit, would have been shipped at a loss under the primitive conditions obtaining at the mine a few years ago. With railway facilities near the mine, costs are reduced and the Company can thus earn substantial profits from ore hitherto regarded as unprofitable. With the new concentrator at work the rate of production will be increased, and this will tend toward still further economy in operating expenses.

Careful laboratory experiments have been conducted for some time on the Messina ores for the purpose of obtaining a definite knowledge of the most economical method of treatment, as well as the probable smelting cost. The treatment of the high-grade copper ores by concentration has presented no difficulties. For years regular shipments of concentrate have been made to Swansea, where this product has commanded a ready sale at the highest ruling market prices, owing to the purity and good quality of the metallic contents. A considerable quantity of material has been produced each month, known as 'jig middling', containing from 10 to 15% copper, which has been accumulated for re-treatment, either by re-grinding and further concentration, or by smelting. In connection with the new concentrator which has a capacity of 250 tons of ore per day, provision has been made for a re-grinding plant to deal with the present middling product. In addition to this, treatment by smelting was some time ago decided upon to turn to profitable account the large stock of accumulated middling, and also to

handle the lower grade carbonate and sulphide ores which are not so susceptible of mechanical concentration as the more massive sulphides. The character of the ores to be treated, and the nature of available fuel and fluxes, have been carefully considered in preparing the design and size of the most suitable furnace. Inasmuch as fine ore, concentrate, and middling had to be treated, it was considered advisable to erect furnaces of the reverberatory type, such as are used in Wales for smelting copper ores. Two furnaces have been erected, each having a hearth 23 ft. long by 11 ft. 6 in. wide, with both furnace flues leading to a 70-ft. chimney lined with fire brick. The fire-boxes have been arranged for burning coal. The slag is drawn into sand-baths and the matte containing the copper, is tapped into iron moulds. The ironwork for the construction of these furnaces has been supplied by Fraser & Chalmers, Ltd. The firebricks which comprise the bulk of the furnace material have been obtained from local makers, and are suitable for this class of work. Special silica firebricks have been

REVERBERATORY FURNACE, MESSINA.

imported from Wales for a start, although it is expected that a suitable quality of brick will yet be made in this country. The capacity of each furnace is about 20 tons of ore per day, for which amount the fuel consumption will be from 7 to 8 tons of small coal. Fuel from the Messina company's coal mine, about 20 miles south on the new railway line, has been found quite suitable. The limestone which is mixed with the ore for fluxing purposes is found in the neighborhood of the mine. The first furnace was started up with a charge of middling, mixed with some roasted copper pyrite containing about 15% copper, and about 5% of lime was added. This charge was successfully reduced, producing a matte containing 65% copper, with 1.5% copper in the slag. Since the initial charge was put through, the composition of the charge has been varied as regards copper content, lime, method of firing, etc. with highly satisfactory results, indicating that the Messina ores can be reduced by this method of smelting to give an average grade of 50% copper matte.

This practice is along the lines of the laboratory experiments. It is expected that the two furnaces will produce about 150 tons of copper matte per month, which at present will be shipped with the mill concentrates. Additions to the smelting plant are already contemplated. A roasting furnace and two additional reverberatory furnaces will be erected in the near future. The treatment of the matte is also under consideration and, with the addition of a refining furnace, blister copper will ultimately be produced, and ingots

containing 96% copper will be shipped.

During August No. 1 furnace turned out 76 tons of matte containing a trifle less than 51% copper. These operations indicate the commencement of serious efforts on a large scale to establish an important copper producing industry in the northern Transvaal. The Messina company, it will be recalled, is controlled by A. M. Grenfell and his associates. Part of the stock is owned by Camp Bird Ltd. and so the mine is affiliated with an American enterprise.

The Technology of Turquoise

By JOSEPH E. POGUE

Turquoise or turquoise, is from the French, meaning Turkish stone. It is generally supposed to have been so called because the mineral originally came to Europe through Turkey. It is more probable, however, that the important locality near Nishapur, in Persia, was once regarded as within the limits of vaguely defined 'Turkey' and the term had reference to the source of supply.

Turquoise is a mineral of superficial origin and is never found in quantity at depths exceeding 100 feet. In consequence, its mining is comparatively simple and inexpensive, for deep shafts and extended tunnels are unnecessary. Deposits, however, are usually confined to arid or desert regions, and many difficulties are encountered in mining them, due to excessive heat, lack of water and timber, and distance from supplies.

Before the advent of gunpowder, the mineral was mined by crude tools, and in some instances its extraction was probably effected by suddenly cooling the heated rock with water. Modernly, however, the material is obtained with the aid of blasting. Where the workings are restricted, a trench or shallow pit usually suffices; but with more extensive operations a shaft is sunk and drifts are driven along the vein. The loosened rock is broken into portable shape and carried to the surface in buckets hoisted by rope and windlass. After further crushing, it is hand picked, with the rejection of all unsuitable material.

Turquoise mines, as a rule, are not fitted with modern mining appliances, due in part to the isolated regions in which many deposits occur, and in part to the frequently temporary nature of the enterprise.

Cutting

Turquoise comes from the mines in rough pieces or nodules, and must be cut and polished before it is adapted for ornamental use. This is rarely done at the mine; the selected material is usually shipped to some trade centre, where the work is done by lapidaries. The most characteristic cut for turquoise, as for opaque stones in general, is the *cabochon*, consisting of flat bottom and polished convex top. Recently, some stones have been prepared with a dull, so-called

'satin finish,' with good effect. The shapes of cabochon stones range from elongated oval to circular, and the convexity or arch varies from nearly flat to dome shape. The turquoise is fashioned into other forms also, such as the pendant, heart, table, keystone, truncated cone, etc., and is sometimes elaborately carved.

The mineral is comparatively soft, and is readily worked. In the United States the customary procedure is as follows. A suitable piece, either selected or sawn from a larger mass by means of a revolving metal disk dressed with an abrasive, is cemented to the end of a slender wooden or ivory holder, and this is pressed against a rapidly rotating wheel or 'lap' of lead or tin on which emery or carborundum powder is spread. The abrading material works its way into the metal surface, which then readily 'bites' the turquoise as a file does steel. The wheel is adjustable to a lathe head and is rotated by foot power or a small motor. The turquoise is kept moving until the desired shape is given the specimen. The cutting wheel is then replaced by one of wool, flannel, leather, or silk, against which the gem receives its final finish and polish.

Turquoise Matrix

The stones introduced to the trade are either pure turquoise, that is, unaccompanied by foreign matter, or turquoise matrix, in which the mineral is cut with attached country rock, quartz, limonite, or other impurities. Attractive patterns and color contrasts are often yielded by the latter, but matrix never commands the price of the pure turquoise. Much material unfitted for pure gems is suitable and used for matrix. Cobweb matrix is a term used to distinguish a blue ground with markings of cobweb pattern. Mottled matrix is turquoise matrix showing two shades of blue or green.

Imitations of turquoise are of three kinds: blue glass or enamel, artificial compounds closely resembling turquoise in composition, and other minerals either resembling turquoise naturally or made to do so by stains or dyes.

Glass imitations are the most frequent counterfeits

of turquoise and are commonly seen in cheap jewelry. Some are crude and obvious, but others are skilfully made and require careful scrutiny to distinguish. Invariably, however, they have a glassy look, are slightly harder than the real mineral, and differ from it in specific gravity. The margin is usually minutely splintered from the grinding, and the small, broken surfaces have a shell-like shape, characteristic of glass. The stone, moreover, is apt to contain air-bubbles or faint flaw lines, indicating that the mass was once molten; and a fragment heated in a hot flame melts to an enamel, while turquoise flies into pieces.

Synthetic turquoise, the most successful substitute for turquoise, is prepared by mixing precipitated hydrated phosphate of aluminum with copper phosphate and subjecting the mass while damp to hydraulic pressure. The product closely resembles the mineral in all its properties and is consequently difficult to detect. The best test is to heat a small fragment in the tip of a hot flame or in a covered crucible; the substitute fuses to a slag, whereas the genuine will fly to pieces. During the past twenty-five years, stones made in the manner described have come upon the market in considerable numbers, particularly in Europe.

Substitutes

Blue chrysocolla is a hydrous silicate of copper which ranges in color from green to turquoise-blue. In its pure state it is too soft for cutting, but when silicified or intermixed with quartz it becomes available as a semi-precious stone. Blue specimens may be confused with turquoise, but the criteria given for copper-stained chalcedony hold also for their distinction. Chrysocolla from the Ural mountains has been cut to some extent, but only recently, and then only slightly has the mineral been so utilized in this country.

Odontolite, which was often confused in the Middle Ages with true turquoise, is fossil bone or ivory impregnated by phosphate of iron, and possesses a blue or green color resembling that of mineral turquoise in daylight, but appearing a dull gray by artificial light. Close examination reveals an organic structure which at once distinguishes it from turquoise. It is seldom encountered nowadays and has small value.

Copper-stained chalcedony, sometimes known as blue chrysoprase, at times resembles turquoise and may be mistaken for it. Its greater translucence, superior hardness, and vitreous appearance serve to distinguish it, however, and a fragment, unlike turquoise, will withstand a high temperature.

Blue dyes have recently been found for chalcedony and agate by means of which the delicate shades of turquoise may be reproduced, and in 1900 the English and French markets were plentifully supplied with stones of this character. Good imitations of this kind are difficult to distinguish without careful examination; they are harder, however, and show greater translucence about the girdle than the opaque turquoise,

and give none of the chemical tests of the latter. A fragment will also withstand a high temperature without flying into pieces. When the coloring is not skilfully done, the specimen presents a crudeness that at once discloses its spuriousness.

Lapis lazuli and azurite in rare instances might be confused with turquoise, but in general the blues of the former are so intense and entirely different from those of turquoise as to obviate deception. If green turquoise were prized by civilized peoples, it would be open to substitution by several minerals, for malachite, green chrysocolla, variscite, and green chalcedony in some instances resemble it closely, but its slight value renders such replacements without purpose.

Improvement in Color

From time to time turquoises come into the trade which have had their color deepened or otherwise improved by artificial means. As such stones are apt to revert to their original shade upon continued wear, they are not sold except in attempts to defraud. Grease and moisture temporarily heightens the color of pale stones, but such expediences do not produce sufficiently lasting effects to be of importance.

The principal procedure to be anticipated is the use of a prussian blue dye. Stones so treated may be detected by washing in alcohol, wiping and soaking in ammonia, whereby the dye is dissolved; or by scraping the superficial coloration from the back of the stone with a steel blade. If the turquoise is valuable, it is preferable to build a small wall of wax on its back and partly fill the depression with ammonia, as the solvent effect can thus be noted at one point only without harm to the specimen. A stained stone is duller by artificial light and more inclined to show a grayish aspect than a stone whose color is original.

The turquoise requires constant care on the part of the wearer in order that its beauty may not be impaired. Its comparative softness and tendency to fade afford ample opportunity for its delicate tint to be marred by carelessness. It should never be worn in contact with other stones, nor permitted to come in contact with perspiration, soap lather, or strong gases. Perfumes are said to have a harmful effect upon its color. Its surface should be kept away from acids or grease of any kind, and should be carefully wiped with chamois skin after handling. The wearer should always remember to remove turquoise rings before washing the hands.

Production

In discussing the turquoise deposits of the world, it will be necessary to consider but four regions which have furnished practically the world's supply of this mineral since the beginning of time. These are the Sinai peninsula; the deposits near Nishapur in Persia; scarcely known localities in central Asia (Tibet and China); and the mines within the southwestern portion of the United States.

But little can be said of the production of the Sinai deposits. The mines were extensively and systematically worked under Egyptian control from the first to the twentieth dynasty, and during this period a great quantity of gem material was obtained. At intervals, for many thousand years, the natives of the peninsula secured turquoises here, part of which reached Egypt and the Continent. Since 1885 the Sinai stones have occasionally made some impress upon the turquoise trade (being known as Egyptian turquoises), but this source has never assumed any great importance in modern times.

It is impossible to approximate the total production of the famous mines near Nishapur in Persia. It is neither known when first they were operated, nor are there records, until recently, of their output. It is certain, however, that for the past thousand years they have supplied nearly all the turquoise used in Europe and until two decades ago in America. Their production, therefore, must have been enormous, amounting to millions of dollars. For the past 30 years the output has varied considerably, but probably \$100,000 is a fair estimate of the annual exports to Europe, though this figure greatly undervalues the retail worth of the stones after cutting.

Information is lacking whereby the extent of the production in central Asia may be judged. It is known that this mineral has found wide application since remote times in Tibet and that this country has furnished great quantities of material. Recently, turquoise matrix resembling that employed in Tibet has appeared on the London and Paris markets. During the past 200 years central China has produced considerable turquoise, most of which has been exported to Mongolia and Tibet. Modernly, considerable turquoise is used in the northern provinces of India, and both Tibet and Persia have contributed to this supply.

Deposits in the United States

The productive deposits of turquoise in the United States are confined to five states: New Mexico, Arizona, Nevada, Colorado, and California; and practically every locality, that has in modern times yielded this precious stone, was exploited of old by the Indians. In the Cerrillos hills of New Mexico, in particular, are extensive excavations made in pre-Spanish times. These workings alone supplied immense quantities of turquoise to the aborigines of the Southwest and were probably the chief source of the turquoise so abundantly used by the ancient Aztecs and allied peoples.

The recent domestic production has been very irregular. During certain years a large output has come from a few important mines, while in other years many deposits have shared in the production. Of late, turquoise matrix has been in great demand, and the large quantities mined have resulted in an overproduction. For this reason, and because turquoise is temporarily out of vogue, many mines are at present

closed. According to statistics gathered by the U. S. Geological Survey, the value of the production in the United States from 1883 to 1911 was \$1,946,460. The figure quoted represents the value of the rough turquoise as purchase by dealers. The value of the cut gems would be several times as great.

Value

The turquoise varies so considerably in value that it is impossible to assign precise rules whereby one can accurately appraise a given specimen. To do this successfully requires both skill in judging quality and knowledge of market conditions.

At present turquoise is somewhat out of fashion in the United States and not very popular. In consequence its market value is down, and \$10 per carat for the best quality is a good price. This applies only to stones of few carats weight; larger ones of the finest grade are worth more per carat. Inferior stones can be assigned no fixed value. Turquoise matrix, according to quality, brings about \$1 per carat. Frequently, however, matrix stones are sold without specific reference to weight and command from 50c. to \$5 each. In Europe the best quality turquoise is worth about \$12.50 per carat.

Grinding Short Zinc Shaving

By J. B. TREGLOAN

A small tube-mill, made from an oil tank such as oil is shipped in, has recently been installed at MacNamara mill, Tonopah, to grind the short zinc from the zinc boxes. The mill runs about 6 r. p. m., and is driven by a belt around the tube. On each end is bolted a 4½-in. flange, into which a short 4½-in. nipple is screwed and keyed, forming the bearings, the feed, and discharge. The inlet nipple is reduced to 1½ in., through which is a 1-in. feed pipe for solution. A few pebbles are used in the mill to grind the zinc a little, and when working, rich solution is allowed to run through and discharge to a pipe leading to the first cell of a zinc box. One test showed 66% of the metal in solution was precipitated in passing through the mill, and the precipitate coming out assayed 55% bullion. Some very fine zinc is left in the mill, but the troubles with short zinc in clean-ups are over. The idea originated at the Tonopah Extension plant, where a barrel, containing a few pebbles set at an angle of 40°, was slowly revolved by gearing. Results show that there is no need of any acid treatment. It is used only a few days each month at the MacNamara, and prevents the short zinc from being coated with white precipitate. It also reduces the cost of cleaning the zinc boxes by about 25 per cent.

The following measurements of different material equal 1 ton weight: Sand, 25 cu. ft.; earth, 18 cu. ft.; clay, 17 cu. ft.; quartz, 13 cu. ft.; earth before digging, 18 cu. ft.; when dug, 27 cu. ft.; and broken quartz, 20 cubic feet.

Accident Prevention at the Nevada Consolidated

By LINDSAY DUNCAN

*Accident prevention in a large industrial plant is a business by itself and requires for its successful prosecution as much care, forethought, and energy as would be required by any other department.

The Nevada Consolidated has attacked the problem vigorously and spared neither time nor money in its effort to effect a material reduction in the tale of death and suffering which has been the inevitable accompaniment of modern industry. The first step was to obtain accurate data of the accidents, and this was done by requiring each foreman to file a report of every accident however trivial, answering the three questions:

(1) What happened? (2) How did it happen? (3) Could it have been prevented? These reports were studied and an earnest effort was made to prevent the recurrence of the same type of accident.

One difficulty which arose was that of meeting new conditions. The metallurgy of copper has advanced rapidly during the last few years, and practice at McGill has kept well abreast of modern methods, with the result that processes have changed greatly during the past six years and new types of accidents have arisen, requiring new safety devices. Thus the huge new basic converters, each of which can blow to blister copper 200 tons of matte in a day, have developed possibilities for accidents which did not exist in the smaller acid converters, and have necessitated a whole new line of safety appliances.

Underground Risks

In taking up briefly the various methods of safeguarding our employees, I will describe a few of the characteristics of the work in each department. In the Veteran mine a top-slicing system is used whereby the ore is taken from the top of the deposit, dumped down raises into ore-bins on the main haulage level at the bottom of the orebody, then trammed to the foot of the shaft, where it is elevated in five-ton skips to the surface. Signs, marked 'Fire Escape', with an arrow pointing the direction of travel, are placed underneath an electric light at all cross entries. At the mouth of the drift leading to the fire escape itself, a large red light is placed. The fire exit is downcast, while the main shaft is upcast. In the fire exit are rest platforms every eighteen feet, on which four or five men can stand at one time. Fire drill is held every two weeks, when all the new miners are required to use the fire exit in leaving the mine.

Three complete Draeger rescue outfits are kept at the head-frame and a selected body of men are trained in their use. A man equipped with one of these

helmets can travel and work in a poisonous atmosphere for a long period of time. Their use and availability in the case of a mine fire would doubtless mean the saving of lives which would otherwise be lost.

The cage in the main Veteran shaft is, of course, equipped with safety-dogs; but in order to be sure that the safety devices are operative, once a week the safety devices are tried, to prove conclusively that everything is in working order.

Risks in Open-Pit Work

Most of the Nevada Consolidated ore is mined by steam shovels at Copper Flat. The risks incidental to mining of this nature fall readily into four classes: (1) those due to the operation of steam shovels and churn drills; (2) those due to blasting and handling of explosives; (3) those due to transportation of ore and over-burden; and (4) shop accidents.

Most of the accidents on the shovels and drills have been due to men getting caught in the machinery. To prevent this, all gears, on both the shovels and drills, have been housed. On the shovels, the crowding and swinging engines are completely enclosed, and also the moving parts of the main engine. The crane-man's seat has been changed from underneath the boom to the bull-wheel, so that now there is no chance for a chain to strike him should it break; and the steam pipe to the crowding engine is run inside the boom and strongly bracketed to prevent its being jarred loose and scalding him. Both drills and steam shovels are well provided with steps and grab irons, which are always kept in good repair and are at once replaced when damaged. The shovels and drills are worked two shifts, and between shifts there is a fireman on duty at each machine. This effectively prevents malicious or irresponsible persons from deranging or starting the mechanism. In case of serious accident the locomotive crane, which is under steam twenty-four hours of the day, can start at once for a wreck and quickly lift cars, timber, rocks, or whatever might be upon an injured man.

Powder handling and blasts have been a prolific source of injury. The Company has appreciated this and in the booklet of rules, issued to each employee of its mining department, sixteen out of the sixty-eight paragraphs are devoted to shops, shovels, and drills; eighteen to train service; and thirty-four to blasting, the use of explosives, and warning signals for blasts. In general these regulations lay down the approved methods of blasting and handling of explosives and counsel safety in every line.

Each shovel and each drill is equipped with a high-grade whistle, one of a different tone being placed on each machine. These whistles are inspected and kept

*Read before the Industrial Safety Conference, University of Nevada, January 27.

up the same as a piece of machinery. Loading, firing, and handling explosives, is done by certain particular employees who are known as 'powder men' and wear distinguishing badges. No others are permitted to officiate, and any unauthorized person handling powder would be at once discharged from the Company's service.

Safety precautions for the train service at the mines, and also at the smelter, are patterned very closely after standard switching practice. Equipment is carefully inspected and promptly repaired; all accidents to equipment, however trivial, are reported and investigated; approved danger signals and semaphores are installed, and as far as possible only experienced men are employed.

Surface Work

Shop accidents are guarded against (1) by making the machinery as nearly fool-proof as possible and then preaching *Caution—First, Last, and Always*. By way of illustration, all emery wheels are cased, circular saws have protectors, all gears are housed, safety set-screws are used throughout, goggles are provided for workmen whose eyes are exposed, motors and switches are fenced in, etc.

Unloading the ore on the concentrator trestle has always been a prolific source of accidents. Ore is received in 55-ton hopper-bottomed steel cars, running in trains of twenty-one or twenty-two cars each, as many as ten trains a day arriving from the mines. The ore as loaded by steam shovels is frequently in lumps several feet in diameter and in the winter season an entire car is sometimes frozen into a solid mass. The ore in fully two-thirds of the cars has to be blasted, and this is done by a special crew carefully instructed in its duties and acting under a definite set of rules for the handling of explosives.

The tops of the bins are protected by heavy iron gratings which effectively prevent any one from falling in while the ore is being discharged. Before the gratings were installed several workmen were injured, both by falling into the bins and going to sleep and then forgetting to wake up before ore was dumped. The stairs, working platforms, and walk-ways of the mill are thoroughly protected by hand-rails. Projecting set-screws on shafting have been removed, and no loose flooring or open hatchways are permitted. In a plant of the size of the Steptoe plant, these simple precautions entailed a vast amount of labor and expense.

The shops of the Company are very complete and include a pattern shop, foundry, tin shop, garage, paint shop, machine shop, blacksmith shop, structural shop, pipe shop, and planing mill. In these shops about 150 men are employed, a fairly large industry in itself. Every emery wheel has a heavy steel plate protector fitted around it, and the saws and planes in the wood shop are similarly protected. Most of the machines are motor driven, and where belts are unavoidable they are boxed in wherever it would be possible for a

workman to come in contact with one. Drip pans are provided to catch the oil from machines so that there can be no slippery places to invite falls. Metal cans with self-closing lids are conveniently placed to receive oily waste. Several chemical fire-extinguishers of approved type are in each building, and on several occasions incipient fires have been extinguished by promptly using them.

The power plant is rated at 10,000 hp. and is actually generating an average of 7000 hp., which is an unusually large output for a plant of this rating. In fact 25 to 30% is the usual ratio of output to capacity, and the 70% output at McGill is an indication that the power plant is worked well up to capacity. The plant consists of nine direct connected engines and eighteen water-tube boilers; ten of the boilers are in the flues of the reverberatory smelting furnaces and utilize the waste heat of the gases.

The power house is the original home of the hand-rail in McGill, and it is encountered on all sides. The switch-board is surrounded by a railing within which no one is permitted except the operator. The metal steps leading to the main engine bearings are not only supplied with hand-rails but the treads are also of rubber studded with lead. This is the same material which has been adopted by the Pullman Car Co. as a standard for the car steps. The stair and hand-rail habit has percolated thoroughly through the entire power plant: fly-wheels, generators, vacuum-pumps, condensers, economizers, feed-water heaters, and boilers are all so equipped.

The steam lines are all strongly anchored and well supported and a leaky steam joint is not tolerated. Superheated steam at high pressure is hard to handle and as a result no liberties are taken with it.

Danger Signals

In case of men working on an electric line, the switch is opened and a sign, "Danger: Men are working on this line," is hung on the open switch. The switch cannot be closed until the man who has been working on the line, and no one else, removes the sign.

The automatic stokers have been a fruitful source of injury to the fire-room labor. Only recently one of the ash-wheelers, in an idle moment, availed himself of the temporary absence of the fireman and essayed to start one of the stokers 'to see what would happen.' He not only saw what happened, but felt one of his fingers depart.

In the smelter, sheet iron protectors have been placed along all elevated hot metal and calcine tracks, to prevent men passing underneath from being burned. All charge hoppers are protected by gratings; hand rails are liberally used and walk-ways and stairs are of substantial and permanent construction.

Signs and warnings in English, Greek, and Slavish are liberally used, and respirators and goggles are distributed to the workmen whose occupations make them necessary.

In the industrial car system, which is used to carry concentrate from the mill to the roaster, calcines from the roaster to the reverberatory furnaces, matte from the furnaces to the converters, and slag and secondaries from the converters back to the reverberatories, many safety devices have been placed, both on the cars and the locomotives. These include chains to prevent slag pots from dumping during transmission, grab-irons and steps, steel running boards, and wooden treads to prevent slipping. An earnest endeavor is made to keep the track up to modern standard. Manganese steel frogs are used on account of better wearing qualities, cast iron frog fillers are used to pre-

vent a switchman catching his foot and being thrown in front of the train. Safety niches have been placed in trestles and places where the trains run with narrow clearance to lessen the danger of a switchman being caught.

The Nevada Consolidated has organized a regular Safety Department under W. H. Droll as safety engineer, and to him I am indebted for much of the information contained in this paper. The Safety Department suggests changes and protective devices, and in general makes it its business to investigate and report on all accidents which occur, or which might occur, around the plant.

The Globe Mine and Mill

By WALLACE MACGREGOR

The properties of the Globe Consolidated Mining Co. are situated near Dedrick, Trinity county, California. The mill commenced operations on November 25, 1913, and at the mines and mills 50 men are employed. The Company owns three groups of mining locations above Dedrick, namely, the Globe, Chloride, and Bailey claims. The Globe mine was located on July 29, 1890, and after being worked for several years, and the subject of considerable litigation, it became the property of the Globe Consolidated company in 1909. Robert Woodburn worked the mine from 1891 to 1899, and operated a 5-stamp mill under great difficulties at the mine, which is situated just over the ridge on the other side of Dedrick. Heavy snows fall at that altitude, and little progress was made then. The Chloride claims were located in 1889 and were first worked with a Huntington mill. The Bailey claims were located the same year, but soon after passed into the possession of the owners of the Chloride group, and the ore from the Bailey mines was crushed in the Chloride mill. About 1897 the Chloride Bailey mines passed to the Chloride Bailey Gold Mines Co., and later were sold to the Trinity Gold Mining Co., which equipped the property, worked the same, and then bonded the property to H. M. Hall, who later transferred his interest to the Globe Mining Co. The present Company bonded the united property from the Globe Mining Co. in the latter part of 1911, and next year began extensive development and equipment of the property held by them under bond. The Company's holdings consist of 36 quartz locations, 3 placer-mining claims, a number of millsites, lots in Dedrick, and power and telephone lines.

The orebodies of the Globe mine are well developed, uniform in value, and have extended to a considerable depth. There is a large amount of ore in sight as shown by development work done by adits, shafts, and cross-cuts. The Chloride mine, on the opposite side of the mountain, has always contained high-grade ore, and the necessary development to be done will

undoubtedly open a large body of high-grade ore. The Bailey mine contains ore of good milling value.

The properties have never before been equipped with a plant sufficient to properly handle and extract the gold from the large orebodies. The present equipment is the latest for the treatment of gold-bearing quartz, and the mill has a capacity of 100 tons of ore per 24 hours. The mine and mill are operated with three 8-hour shifts. The ore now being crushed is taken from the Globe and Brown Bear claims. Richard James is foreman at the mine.

The ore is taken out through a cross-cut at the Globe mine and transferred to the ore-bin at the top of the main aerial tramway, 6000 ft. long, with a 2500-ft. drop and 35° slope. It is then conveyed to the mill in buckets of half-ton capacity each. On arriving at the mill it is dumped into an ore-bin, weighed, crushed, sampled, and delivered to the storage bin behind the stamp-mill. The return buckets on the aerial tramway carry all necessary timber and freight to the mine.

The mill is a 20-stamp, all-sliming, cyanide plant, with a capacity of 100 tons per day. It covers an area 225 ft. long and 66 ft. wide, on the steep slope of the mountain, and consists of eight distinct sections under cover, namely, crushing, sampling, stamping, separating, tube-milling, agitating, filtering, precipitating, and pumping. It is the finest and best equipped plant of the kind in the state, and was constructed by J. W. Rutherford.

The plant is driven by water-power, the water being conveyed from Canyon creek through a ditch 6860 ft. long and 3700 ft. of 20 and 18-in. pipe, and is brought to the mill under a head of 600 ft. In each department of the mill there is a separate water-wheel which furnishes power to that department.

The ore is crushed in cyanide solution through coarse screens. There are no copper plates used. From the batteries the pulp goes to a Dorr classifier and the coarse sand is separated from the slime. The sand

goes to the tube-mill for regrinding, and the slime goes to thickening tanks for settling. The reground sand returns to the classifier by a bucket-elevator for reclassification. The final product is next agitated in Dorr agitators. After several hours of agitation, the pulp is transferred to more thickeners, the clear solution overflow containing the gold. This is precipitated by zinc shaving. The thickened pulp is sent to an Oliver filter which extracts the balance of the cyanide solution and dissolved gold, the waste pulp being transferred by belt-conveyor to the dump. The spent solution from the zinc-boxes flows to sumps, where it

ferred to a site near the mill. There is also a saw-mill with a capacity of 10,000 ft. per day, together with all necessary equipment, driven by water power. The logging is done by a water-power hauling system. This sawmill was used for making the lumber for the mill, boarding-house, office, and other company

AERIAL TRAM FROM MINE TO MILL.

THE GLOBE MILL AND CYANIDE PLANT.

is made up to strength and pumped back to the battery tank, to again enter the continuous circulation through the plant.

The tailing discharged on the dump contains from 40 to 70c. in gold per ton. The value of the spent solution in the sumps is 5c. in gold and about 25c. in cyanide per ton. This is saved in the continuous circuit solution. No cyanide escapes from the mill, and no cyanide is discharged with the residue. H. S. Payson is mill superintendent.

The property is also equipped with an electric power and air compressor plant, the latter furnishing power for drills and will also furnish the necessary power for the air hoists. A new compressor is to be installed near the mill. The electric plant will also be trans-

ferred to a site near the mill. There is also a saw-mill with a capacity of 10,000 ft. per day, together with all necessary equipment, driven by water power. The logging is done by a water-power hauling system. This sawmill was used for making the lumber for the mill, boarding-house, office, and other company

buildings, and also for mining uses. The timber was obtained from the National Forest, and during all the time of the manufacture of the same the business relations between the Company and the Forest Service officials were very pleasant.

The Globe Consolidated Mining Co. is incorporated under the laws of Arizona. J. B. Goodhue, of Derby Line, Vermont, is president, and T. M. Craig, of Sherbrooke, Canada, is treasurer.

Rubber exports from the Amazon district, South America, during October 1913, were 6,995,915 lb., compared with 9,032,657 lb. in the same month of 1912. Prices were low and financial conditions at Para were unpromising.

Antimony: Its Ores, Metallurgy, and Uses

By L. C. MOTT

*The beginning of the antimony industry in America was at the plant of the Mathison Smelting Co., in San Francisco, established some time in the 80's and removed to Staten Island, New York, about 1893. The San Francisco plant obtained its ores from Nevada and various mines scattered throughout southern California. The high freight rates then in effect made the industry a purely local one; but the local market not being of sufficient importance to induce capital to go into it on a large scale, it became necessary for Mathison and company to move to Staten Island, New York, where they erected a plant to treat foreign ores. This plant continued for some time to treat ores from Mexico and other parts and finally went out of business. At the present time all the antimony produced in the United States is that obtained from the lead refineries as a by-product, and only amounts to about one-tenth of the antimony consumed in this country.

Source of Antimony Ores

France, Algeria, Italy, Mexico, China, and Australia, besides several other countries, produce antimony ores. For a great many years France was the largest producer, but of recent years China has taken the first place. The antimony mines of the different European countries are rapidly nearing exhaustion. The ores being treated at present are of low grade. The largest deposits of China now worked are situated in the far inland provinces. These ores are roughly concentrated by liquation and shipped to the markets of Europe and America. England, France, and Germany are the countries producing the refined metal at present time. The only country that the United States need fear as a future competitor for antimony ores is China; but with a better understanding of the metallurgy of antimony, and with the present better means of transportation, many of our western antimony deposits should be able to produce this metal at a lower price than that at which it can be imported into this country.

Of the ores of antimony, those most commonly found are those which contain the sulphides or the oxidized sulphides of antimony. There are two compounds of sulphur and antimony, the trisulphide and the pentisulphide. The trisulphide is known in both the crystalline and amorphous state. The crystalline sulphide is the ore found in nature and is known as antimony glance, or stibnite; it has a metallic lustre and a grayish black color. The amorphous trisulphide can be obtained by artificial processes and is of a red or orange color according to its method of preparation. Kermes mineral, or the red trisulphide, can be prepared by boiling antimony glance with carbonate of

soda or potash. The passing of sulphuretted hydrogen through a solution of antimonious salt precipitates the orange colored trisulphide. Antimony glance, or stibnite, contains 71.4% antimony and 28.6% sulphur. It is seldom entirely free from other metals such as arsenic, lead, or zinc.

Native antimony is occasionally found, but never in large enough quantities to be of commercial importance. Antimony oxide (Sb_2O_3) is the most important source of antimony apart from the sulphide. It is dimorphous, the cubic form being known as senarmonite and the rhombic form as valentinite. It contains 83.4% antimony and 16.6% oxygen. It is the product of the weathering of antimony sulphide and occurs in the upper portion of antimony ore deposits. It seems very probable that the only situation in which one could expect to find extensive bodies of the oxides would be in or near limestones or similar formations.

There are numerous minerals in which antimony occurs, but not in sufficient quantity to make them a commercial source of the metal. Among these minerals are: antimony ochre or cervantite (Sb_2O_4), and antimony blend, or pyrostibite ($2\text{Sb}_2\text{S}_3 \cdot \text{Sb}_2\text{O}_3$) which contains 75% antimony, 20% sulphur, and 5% oxygen. Many of the ores of gold, silver, copper, and lead contains varying quantities of antimony.

The development of the metallurgy of antimony has been slow for various reasons, the principal one being that until recent years the consumption was not sufficiently great to induce a careful search for new methods. A plant that produced a thousand tons of the metal per year was the exception rather than the rule. The small furnaces that were developed in Europe for the smelting of lead and copper ores were very crude and inefficient compared to our modern American plants. As long as the antiquated methods were sufficient to produce all the metal that was needed, there was but little incentive to improve; but under the spur of increasing uses and needs there has recently been a rapid advance.

Early Method of Treatment

The old method for the treating of sulphides, and one that is still in common use in some parts of the world, consisted in melting them in silica or graphite pots. The ore was introduced into a small pot usually holding not more than 50 lb. This pot had small holes in the bottom and was placed directly over another smaller pot which was sunk in the sand to keep it away from the direct flame. A roasting stall or furnace was built about the upper pot and a small fire started; after several hours the antimony sulphide would have liquated out and run into the lower pot. The extraction was poor and the fuel consumption high. This liquated

*Abstract from a paper read before the Los Angeles section, American Chemical Society.

material then had to be re-smelted with light iron scrap and salt to remove the sulphur. This was done in graphite crucible. The product was known as 'singles' and contained about 91% Sb, 8% Fe, and 1% S. This was again re-smelted, the new charge consisting of about 93% singles, 5% liquated antimony sulphide, and 2% salt. After about one and one-half hours heating it was stirred with an iron rod and carefully poured under a slag cover. The product was known as 'doubles', and contained about 98% Sb, 0.2% Fe, 0.2% S, with various other small impurities. To purify further it was necessary to add potash and sulphide of antimony and re-smelt.

As the demand for antimony grew larger it also became apparent that some new and more economic method of production had to be obtained. About this time a method was perfected for the treatment of sulphide ores under an iron bath in a reverberatory furnace. The furnace did not differ greatly from a small modern reverberatory. In this process, first, a bath of ferrous sulphide was smelted on the hearth of the reverberatory furnace; next, the antimony sulphide ore was dropped into this and rapidly rabbled so that the ore was thoroughly mixed with the bath. At this point wrought iron scrap was added in sufficient quantity to precipitate the metallic antimony. The temperature was kept fairly high; the antimony was tapped from under the sulphide cover into moulds. The greatest objection to this kind of a furnace was that it produced a product that had to be refined further.

The Direct Process

A little later two Frenchmen, taking advantage of the easy volatilization of antimony, evolved a process that produced a commercial product direct from the ores which could be easily and inexpensively reduced to the metal. They worked along different lines, but the basis of their ideas and patents was the introduction of ores with either coal, coke, or charcoal direct into a shaft furnace. The furnace was connected by a series of cooling and condensing flues with an exhaust fan. Most of the metal was precipitated as an oxide in the flues and the remainder blown through a coke-tower over which water was sprayed. The cardinal principle of both of these processes was the formation of the volatile oxide by controlling the volume of air. This was done by varying the speed of the fan and controlling the thickness of the ore charge. One of these methods claims to recover 95% of the antimony in the ore and to produce a product that is 99.6% pure. This process has proved eminently successful in France. Such troubles as are encountered are purely mechanical and are easily overcome. The process has, moreover, this great advantage that one can successfully treat ores containing other valuable metals. Lead, copper, gold, and silver are left with the scoria and can later be extracted. Arsenic, the great bogey of antimony, would be eliminated as it is more volatile than antimony and would be carried farther along before being precipitated.

This process of smelting oxide ores was none other than that used in a modern lead furnace, but it had to be modified to some extent before it worked successfully. The column was raised and the blast pressure was higher than that of the average lead smelter blast, but in all there was not any great change. The product was not pure, ranging from 93 to 97% antimony, and had to be sent to Europe for refining; but it was a great improvement over the old pot method, and thoroughly demonstrated that the oxides could be smelted. The reduction of the precipitated oxide to metal in the volatilization process was obtained by mixing with soda ash and coke breeze, or charcoal, and slowly melting in pots or in a reverberatory furnace.

Antimony is used largely for type metal. English type metal, for example, contains 25% antimony. Antimony is used in the manufacture of babbit and other anti-friction metals, the amount used varying from 11% to as high as 25% antimony. It is used in pewter, which contains 11% antimony. The anti-friction match, which has come into such universal use of late, contains 25% antimony sulphide in the heads, and the smear on the box 53%. It is used in medicine in the form of tartar emetic, and other products of pharmacy. Large quantities are used in calico printing and dyeing. It is used largely in the ceramic arts. A patent has recently been issued covering the use of antimony in the place of tin for the manufacture of bath-tub enamels. It is the base of a very high-grade paint, both in the form of the oxide and the amorphous trisulphide, the latter being used for ship paint. Large amounts of antimony sulphide are used in vulcanizing rubber, especially for automobile tires, it having the advantage of not changing by weathering or sunlight.

The latest statistics show a consumption of about 24,000,000 lb. of antimony and its salts in the United States in the year 1912. All of this, apart from that contained as a by-product of the lead refineries, dross, and old metal scrap, is imported from abroad.

A Small Air-Blast

Below is a figure illustrating a simple small air-blast run by water and used for ventilating a 3000-ft.

adit with raises and drifts. A smaller blast of the same sort might be used for a blacksmith forge. The apparatus can be easily improvised at any mine.

Transportation and Government Regulations in Bolivian Tin Fields

By G. W. WEPFER

All the South American countries have adopted the metric system, but in practice they use mostly the old Spanish system. The following conversion table shows the relation between the old Spanish units and the present standards:

- 1 metric ton = 10 metric quintals = 21.734 Spanish quintals.
- 1 Spanish ton = 20 Spanish quintals = 920.80 kilos = 2000 libras.
- 1 English ton = 1015.938 kilos = 2240 lb. English = 20 cwt. @ 112 lb.
- 1 metric quintal = 100 kilos = 220.47 lb. English.
- 1 Spanish quintal = 46 kilos = 101.40 lb. English (accurate, 101.4116 lb. English).
- 1 English quintal = 50.7969 kilos = 112 lb. English.
- 1 hectare = 10,000 square metres = 2.4711 acres = 1 pertenencia.
- 1 cajon = 50 Spanish quintals = $50 \times 101.4 = 5050$ lb. English (say 5000 lb. avoirdupois).
- 1 marco (weight) = $5070.58 : 10,000 \times 0.507058$ lb. avoirdupois (say $= \frac{1}{2}$ lb. English).

The contents of silver in ore is not given in per cents. but always in the number of marcos per cajon of ore.

The superintendent of the Bolivian Customs states that the amount of tin exported in 1912 amounted to the value of \$23,289,732.

Bolivian Export Duty on Tin

Based upon the price of Straits tin, which is obtained every two weeks from London the corresponding duty remains unchangeable for two weeks.

| Price of straits tin in £ per ton. | Concentrates. Duty per 100 kg. | | Tin bars. Duty per 100 kg. | |
|---------------------------------------|-----------------------------------|-------|-------------------------------|------|
| | \$ | Bs. | Bs. | \$ |
| Up to 100..... | 0.80 | 2.00 | 3.25 | 1.30 |
| 100 to 110 | 0.88 | 2.20 | 3.50 | 1.40 |
| 110 to 120 | 1.14 | 2.85 | 4.37 | 1.75 |
| 120 to 130 | 1.40 | 3.50 | 5.24 | 2.10 |
| 130 to 140 | 1.66 | 4.15 | 6.11 | 2.45 |
| 140 to 150 | 1.92 | 4.80 | 6.98 | 2.79 |
| 150 to 160 | 2.18 | 5.45 | 7.87 | 3.15 |
| 160 to 170 | 2.44 | 6.10 | 8.74 | 3.50 |
| 170 to 180 | 2.70 | 6.75 | 9.61 | 3.85 |
| 180 to 190 | 2.96 | 7.40 | 10.48 | 4.20 |
| 190 to 200 | 3.22 | 8.05 | 11.35 | 4.54 |
| 200 to 210 | 3.48 | 8.70 | 12.22 | 4.90 |
| 210 to 220 | 3.74 | 9.35 | 13.09 | 4.24 |
| 220 to 230 | 4.00 | 10.00 | 13.96 | 5.58 |
| 230 to 240 | 4.26 | 10.65 | 14.85 | 5.94 |
| 240 to 250 | 4.52 | 11.30 | 15.70 | 6.28 |
| 250 to 260 | 4.78 | 11.95 | 16.57 | 6.63 |
| 260 to 270 | 5.04 | 12.60 | 17.44 | 6.92 |
| 270 to 280 | 5.30 | 13.25 | 18.31 | 7.32 |
| 280 to 290 | 5.56 | 13.90 | 19.18 | 7.67 |
| 290 to 300 | 5.82 | 14.55 | 20.05 | 8.02 |
| 300 and up | 6.08 | 15.20 | 20.92 | 8.37 |

In this table the value of the Boliviano is taken at \$0.40 gold.

In the article published last week I gave the beginning of the mining industry as 1548. The settlement of

La Paz was due to the discovery of the great mineral wealth of the country. The Spanish statistics were started in Potosi in 1545, recording accurately the production of gold and silver mining in Bolivia. The Spanish silver production from 1545 to 1800; that is, in 255 years, amounting in U. S. Cy. to \$3,339,262,000. The production from 1800 to 1825 (the date of Independence) was \$67,104,000, and the total Spanish silver production, 1545 to 1825, in U. S. Cy., \$3,406,366,000. The Spaniards were not laggards, they worked fast, not knowing how long their stay would last. They wanted to get the most of the treasure in shortest time. This is also evident from their manner of mining. Trained men were sent out to hunt for natives to work in the mines and for women to cultivate the fields and to raise crops for the population to live upon. The old records in connection with mines always speak of two special classes of men, the Conquistadores and the Jesuits. The Conquerors were the Rulers, the Jesuits were the mining engineers. At the time the Spaniards had to leave, they had more than 10,000 silver mines, all producing. There were 5000 tunnel mines on Mount Potosi. Many times great difficulties were experienced with flows of water in the mines, but these were overcome and no mine was lost or had given out.

Sr. José Maria Dalence was requested by the government in 1848 to visit all the mining districts and report on the condition of the mines. He has published his report in a book entitled 'Bosquejo Estadístico de Bolivia', in 1851, and after careful investigation he gave detailed reports which show the number of silver mines abandoned, 10,000; the number of silver mines operating more or less feebly, 135; and the total number of silver mines, 10,135.

The Bolivian government statistics state that these figures hold good to the present date and the reason of the increased production is mainly due to improved methods in working. Regarding gold mines, Sr. Dalence gives the number of mines abandoned as 1300; gold mines in operation, 13; total number of gold mines, 1313. The condition of these gold mines has not changed since the time of Sr. Dalence. Any of these abandoned mines can be obtained for working on perpetual leasehold; that is, as long as the taxes are paid. The mine tax amounts to Bs. 2 (\$0.80) per hectare (10,000 square metres = 2.4711 acres) every six months. A certificate also has to be obtained for all the hectares contained in the mine ground. This certificate costs Bs. 10 (\$4). The Spaniards, after burying their treasures of gold and silver, left the mines in a body. A few stayed behind as caretakers until the others would return. These few men were murdered by the Indians in retaliation for the treatment the Indians had received. The portals of the mines

were closed, the reduction works were destroyed, and the Indians placed guards on outposts, that no white man might come near to take notice of the changes. The Spaniards had no wagon roads, only trails. When the rainy seasons came the trails were overgrown with bushes and trees. The farms were not cultivated so that the Indians could not find sufficient food and migrated to other parts of the country.

Records of Lost Mines

At the town hall in the city of Potosi which had a population of 200,000 before the city of Boston, Mass. was founded, the production records were kept of all the mines, so that the 'Royal Fifth' could be collected and year by year could be sent to the treasury of the king of Spain. This record is now in the government archives at La Paz. From this record it is found that in the province of Inquisivi there are 160 abandoned mines and only five in operation, mines which according to record had furnished bonanzas in their days. Sr. Dalence, provided with old maps, endeavored to find some of these abandoned properties in the mining district of Chuquicamiri, especially the great mine of 'San Juan Bautista', which was destroyed by the Indians after the revolt of the 12th of June, 1666, but was not successful. The whole district was depopulated and no guides could be found to aid in their discovery. There is a standing reward offered by the Government for the discovery of these mines, yet no prospector could be found with sufficient means to relocate them. There are good stage roads built and maintained, as the road from La Paz to Chililaya (the harbor Puerto Perez) Lake Titicaca which is 45 miles long; La Paz to Oruro, 150 miles; Oruro to Cochabamba, 123 miles; Oruro to Lagunillas, 135 miles; Cochabamba to Sucre, 195 miles; and Potosi to Sucre, 77 miles long. Roads from Uyuni to Tupiza, and Tupiza to Tarija, and others are in course of construction. The roads are built as in the United States. Every citizen has to work for two days on the public highways, or pay the road money, which amounts every year to Bs. 1 (\$0.40). The Indians build practically all the roads.

Concentrates and bars are generally conveyed by llamas from the mines to railway stations and placed in charge of agents. These agents consign the same to shipping agents at the sea ports of Antofagasta, Mejillones, Arica, or Mollendo with instructions. The seaport agents, advised by naval gazettes of coming ships in advance, contract for space for concentrates or bars, so that as soon as the ship arrives, the freight is put on board without delay. Small mine owners with only small funds consign their freight to the nearest commission merchant, who attends to all the shipping by his own agents, and who also advances the freight charges, etc., for which services he charges a high commission, as he has to wait for his money until the concentrates or bars are sold in the United States or Europe.

Besides the direct railways from Oruro to Guaqui on

Lake Titicaca there are two other ways to ship concentrates or bars to Lake Titicaca. The Peruvian Corporation, Ltd., of London and Lima owns the railway from Mollendo to Puno on Lake Titicaca, and all the lake steamers, and has received from Bolivia a franchise to maintain steamships and barges on the Desaguadero river. This river is navigable for 350 miles from the Lake Titicaca, port Desaguadero, to near the city of Oruro. This corporation will accept the concentrates and bars of copper, silver, and tin at any point from near Oruro and deliver the same at the Port of Mollendo. The second opportunity is the conveyance of freight by llamas to Lake Titicaca at the port of Chililaya, and from there by the Peruvian Corporation across the lake and down to Mollendo. This route takes more time but is the cheapest.

A llama will carry 100 lb. and costs nothing for feed. A donkey will carry 150 lb, but has to be fed and the feed has to be taken along. The comparative cost, for example, from Oruro to Arica on the coast is:

Per 100 lb. per llama, requiring 30 days, about \$1.25 U. S. Cy.

Per 100 lb. per donkey, requiring 12 days, about \$2 U. S. Cy.

Per 100 lb. per mule, requiring 5 to 7 days, about \$2.75 U. S. Cy.

The descent from the Western Cordillera is very steep and this part of the railway was expensive to build and place in operation. It is a question whether the railway can establish a freight rate that can compete with pack animals and with the rates of the Peruvian Corporation.

A case is known where a custom smelter has been re-located near a railway, the respective mines of copper and silver being further up in the Cordillera. This Company built an expensive railway to the mines and now at the lowest possible freight rate the Company finds that it cannot in every case compete with the llama, which takes a shorter and steeper trail.

Alluvial Washings

There is but very little done in placer mining, and what there is, is done by small parties with but little capital and is not conducted in a systematic way. There are large masses of debris rich in tin, and sometimes tin and gold at the foot of ravines where the placer deposits occur. In the summer mountain torrents rush down these ravines and in the winter, at high altitudes, the sun will only melt the ice for about three hours a day, which furnishes enough water for washing. Where there is a moderate amount of water the ground is dug up and the larger pieces, or whatever can be sorted out by hand, is recovered. The fine material is washed in a hand jig which can be used to advantage for this work. In the winter and when there is not water the material has to be carried by llamas to the nearest place where water can be had for the washing of this material. Most of the work has to be done in winter, as when the torrents appear nothing can be

done. The great mass of tin placers will be left untouched for the future times.

Dumps of tailing, heaps of waste of low-grade ore and scoria, are also a great asset for future times. No mine taxes have to be paid on these deposits. They only have to be registered. These dumps contain all the tin from silver mines which was thrown out by the Spaniards together with low-grade silver ore. There are large slag heaps everywhere; at Oruro are the large accumulations of slag with 30 per cent of tin and 20 per cent of lead and silver. Most of the tin is shipped in the form of concentrates, only a few companies ship the tin in bars. Besides these, there are a number of small custom smelters which smelt the ores of small producers. These furnaces are small water-jacketed furnaces. They use charcoal fuel and *taquia* (the dung of llamas). *Taquia*, used for the roasting and smelting of ore, is cheap. It is collected by Indians and is sold for a few centavos per hundred weight.

In the Chorolgue district, North Chichas, Department of Potosi, 175 tons of concentrate give about 105 tons of bar tin. Tin bars as a rule are very low grade and are merely made to reduce freight cost. Where tin bars are made which have to be carried by llamas, each bar has to weigh not more than 50 lb., so that the llama carries in the pocket of the pack-saddle on each side, one bar, making together 100 lb. as the load for one animal.

Granulating Copper Matte

By R. L. HALLETT

*The process described was installed by B. H. Bennetts at the Humboldt plant of the Consolidated Arizona Smelting Co., Yavapai county, Arizona. The blast-furnaces were charged with a low-grade copper ore and the resulting matte was so low in copper that a second concentration was necessary. The original method of operation was to make a regular matte-run concentration in the blast-furnace, as is usually done. The matte resulting from this run went directly to the converters, but the operation was costly and the matte not quite as high in copper as was desired. The object of this article is to describe briefly the method which was used in place of the blast-furnace concentration for treating the first-run low-grade copper matte.

The matte was taken directly from the blast-furnace settler in the molten condition and granulated with water. The granulated matte was roasted in Edwards furnaces and then charged hot into the reverberatory furnaces. This gave a reverberatory matte high in copper and desirable for treatment in the converters. The cost of granulation and roasting was not excessive, and this method of treatment was found to be a profitable one. The apparatus used and the method of operation will be understood from the accompanying

figure, which is a vertical section of the granulating unit. The molten low-grade matte, from the settler, was brought by the electric crane and poured into an old V-shaped cast iron slag pot supported by a steel framework. Four tons of matte was poured at one time. The matte ran through a 1 $\frac{1}{8}$ -in. hole in the bottom of the slag pot into a short launder, and from there into a long one leading to the settling tank. Two streams of cold water, one above the other, issuing from fish-tail nozzles, struck the stream of matte as it fell from the short launder, solidifying and granulating it and carrying it into the settling tank. The granulated matte settled perfectly in the settling tank and the clear water overflowed continuously. The water was turned on only when matte was being

SECTION OF GRANULATING DEVICE.

poured. When the settling tank was full, the water was thoroughly drained by removing plugs from a vertical row of screen-covered holes down one side of the tank. The settling tank was made of wood, with a hopper bottom, and discharged into a car. The discharge hole was covered by a swinging door, battened down and made tight by means of a heavy rubber gasket. The water for granulation came from a high-pressure pump, through a 4-in. pipe which fed the two 3-in. pipes connected with the nozzles. The water was under a pressure of 60 lb. per square inch, and 900 gal. of water was required for granulating one ton of matte. The pump was automatically regulated to deliver constant pressure by means of a Fisher governor. The short launder was an iron casting, and the long one was lined with cast iron. The matte was granulated to about $\frac{1}{4}$ in. and under. There was practically no oxidation during granulation, the sulphur content decreasing only about 0.3%. After draining off the water, the granulated matte was drawn into cars and taken to the roasters.

In the smelting of low-grade copper ores this process is worth considering, and under favorable conditions it may be found the most desirable method of treating the first run of low-grade matte. Granulation can be used for lead matte as well as for copper.

*Abstract from the Colorado School of Mines Magazine.

Dredging at Oroville

By M. W. VON BERNEWITZ

To obtain a proper idea of the amount of work done,

Helman, superintendent of the El Oro Dredging Co., and who marked in the areas remaining to be dredged in the accompanying cut, I studied the present situation at Oroville. There are 16 dredges working, but it is safe to say that within six months there will be

being done, and to be done in this well known district, one has to cover the area in an automobile or buggy, and be careful he does not get lost among the 21 square miles of dredge tailing. In company with Charles

only 13, as one boat owned by each of the Oroville, Ophir, and Pennsylvania companies will soon have finished its respective area. Narrow strips of gravel are still left on each side of the field, as indicated.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

California Miners and the Exposition

[The discussion of plans printed under the above title in the *Mining and Scientific Press*, January 31, has called out the following interesting letters, addressed to Mr. van Barneveld. We print them in the hope that they may serve to stimulate further interest in the project.—EDITOR.]

My dear Sir—I have read with interest your suggestions, in the last issue of the *Mining and Scientific Press*, for a collective and consolidated California mining exhibit in the Palace of Mines and Metallurgy. Because of no appropriation for a state exhibit, I fully agree with your conclusions that the counties should merge their efforts in a thoroughly representative and general educational exhibit, rather than in the usual scattered form of individual county fair exhibits that leave no lasting impression. I sincerely hope the mining counties and the mining industry of the state at large will coöperate with you in carrying out your suggestions, which I feel confident are the very best possible under the circumstances.

F. W. BRADLEY.

San Francisco, February 3.

Dear Sir—I have read with interest your article in the last issue of the *Mining and Scientific Press*, entitled 'California Miners and the Exposition.' I am heartily in accord with your views in this matter, and I very much hope that you will succeed in your effort to persuade the counties to coöperate in the carrying out of your plans.

ARTHUR GOODALL.

San Francisco, February 3.

Dear Sir—I have just read your article, 'California Miners and the Exposition,' in the last issue of the *Mining and Scientific Press*, and wish to say that the method of making exhibit as proposed by you I feel sure is to the best interests of the mining counties of the state, and will prove of most interest.

LOUIS ROSENFELD.

San Francisco, February 2.

Dear Sir—Your splendid article in the *Mining and Scientific Press* for January 31, 1914, entitled 'California Miners and the Exposition,' has been called to my attention, and I have read it with delight. It has in it the elements of proportion, completeness, and common sense, that are quite refreshing after the many suggestions of disorganized county exhibits that have been exploited. Unless we have at the Panama Expo-

sition an educational exhibit in some such concrete form as you suggest, in some way coördinating the exhibits of the respective phases of the mining industry, such as placer mining, copper mining, oil mining, gold-quartz mining, etc., the exhibition will have no attraction for the general public, and will be void of educational effect. To have no collective exhibit, or no exhibit that could be put forward in some such spectacular form as you suggest, would mean an aggregation of isolated county exhibits, interesting, it is true, to men who are familiar with the details of the mining industry, but a matter of utter weariness and no educational value to one who is not a mining man, and if too extensive and too multiplied in character, of no absorbing interest even to a mining man. By all means, no matter what individual exhibits certain mining counties may feel constrained to make, on account of local conditions, let them all coöperate in sufficient degree to bring about the splendid collective educational exhibit foreshadowed in your article.

JOHN F. DAVIS.

San Francisco, February 3.

Dear Sir—I have read with interest your recent article relative to an exhibit of the mineral industry of California. The suggestion made appears to me to be a good one, especially to attract the attention of people who know nothing of these matters and who might by this pictorial representation get a general idea of the industry. For those who are looking for investment, there should in addition be provided statistical information, so arranged and presented as to attract and hold their attention, until they become interested enough to make inquiry and obtain more definite information. This could be done by projecting on a screen pictures of dredges in operation, of hydraulic operations, stamp-mill interiors, underground flashlight pictures, mine hoists in operation, drag-line machines, washing plants, cyanide operations, oil wells, drilling, spouting, and pumping, pipe-lines, loading racks, trains of oil cars, refineries, and finished goods in packages, interspersed with statistical statements as to individual and collective outputs, profits, and details of men employed: in fact, a complete picture show, depicting all the different operations actually going on. In no other way that I can suggest, can any adequate and rapid idea be given of the nature, extent, methods, and value of the mineral industry.

S. A. KNAPP

San Francisco, February 3.

Water in Veins

The Editor:

Sir—The letter from James F. Kemp, appearing in your issue of December 13, is so disarming that not much appears left for me to say. However, in order to complete the record I venture to point out that in my friendly protest I did not claim priority so much as recognition. I have no further quarrel with my

friend at Columbia University on the score of priority. He is deservedly welcome to it, but does that explain why he, with Messrs. J. W. Finch and W. H. Emmons, should have failed to refer to my numerous writings on this particular subject? Obviously, not. It was probably an accidental oversight, and I am content to leave it at that.

T. A. RICKARD.

London, January 21.

The Rand Banket

The Editor:

Sir—Although I have already contributed to this discussion, I shall be obliged if you will allow me to make the additional remarks contained in this letter. I have no desire to enter into polemics on the subject of priority, but the last of Mr. Horwood's articles (published in your issue of December 27) contains a passage which must call for comment on my part, since it is implied therein that my ideas on the Rand banket owe their origin to a perusal of Mr. Horwood's paper. The passage referred to is on page 1006 and reads as follows: "Since the writer has in the above papers emphasized the similarity of the bankets to ordinary gold-quartz veins—others have gradually adopted the same view; for example, Hatch wrote in 1911 as follows: 'The origin of the gold in the Witwatersrand banket has been referred to as one of the greatest riddles of modern times, but evidence is slowly accumulating to prove that the Rand banket is not a fossil 'placer', but rather that its gold has an origin similar to that of quartz veins'." ("Types of Ore Deposits").

That my ideas on this subject were not borrowed from Mr. Horwood (who came out to the Rand as my assistant in 1903 or 1904 and first wrote on the subject in 1905), but rather the reverse, will be made sufficiently clear, I think, by a quotation of the following passage from my paper on the 'Geology of the Witwatersrand' read before the Geological Society of London in 1897.*

"Examination under the microscope shows that the cementing material of the conglomerates consists of a mosaic of minutely granular but distinctly crystalline quartz. The rock is so firmly knit together by this secondarily deposited silica that, when broken, the fracture passes irrespectively through pebbles and matrix. In places the newly deposited quartz has grown on to the pebbles in such a manner as to obliterate their original margin and to produce a rock resembling a homogeneous and glassy variety of vein quartz. Of other minerals, finely divided iron pyrite is the most common, being disseminated through the matrix of the rock in fine crystalline particles; and native gold, when present, is in intimate association with this mineral. Galena, blende, and copper pyrite occur, but rarely. In the surface rocks, down to about 100 ft., the sulphides of iron are replaced by the oxides of that metal. The silicification, or more generally the

mineralization, of these conglomerates is, in my opinion, the result of secondary processes of infiltration and crystallization. It is significant in this connection that when most mineralized the conglomerates are often seamed with veins of white quartz; and there can be little doubt that these veins were formed in connection with the mineralization of the conglomerates. There is no reason for ascribing a special method of origin to the gold; and I hold, therefore, that the gold has been introduced with the pyrite with which it is in intimate association, as a part of the general process of mineralization, and I cannot agree with those authors who describe the conglomerates as deposits in which the gold was either pre-existing (alluvial gold) or was introduced contemporaneously with the deposition of the pebbles and sand."

Thus, already in 1897, not only did I point out that by intense silicification the banket had assumed the character of a quartz vein, but I also drew attention to the intimate genetic connection of the gold with the pyritization of the beds.

F. H. HATCH.

London, January 12.

The Editor:

Sir—In the *Mining and Scientific Press* for January 31, Kirby Thomas, in writing of the Rand Banket and the relations of the ore deposits on the Rand to dikes, brings out some interesting and significant facts regarding the veins at Cobalt and Kirkland Lake in Ontario. He cites various other regions within which deposits supposed to the 'unique' may conceivably have been formed in connection with the intrusion of igneous dikes and ends by asking whether such a genesis cannot be conceived in connection with the Wisconsin lead and zinc deposits. It can, but gratuitously; just as anyone can imagine for himself a rich Uncle in the Klondike. But such imaginations bring but small heritage.

Writing in 1910,¹ I summarized the objection to such a hypothesis as follows: "Their derivation through igneous agencies is excluded by (1) the known absence of any intrusive or extrusive igneous rocks of as late or later age than the rocks in which the ores occur; (2) by the presence under the area of unbroken sheets of artesian water in sedimentary beds, precluding the rising of heated solutions from depths into these beds without dissipation; (3) the absence of faults or fissures reaching down into the lower beds, an absence confirmed by the presence, as stated, of underlying artesian waters; and (4) by the positive and sufficient evidence of the origin of the ores by other agencies." Fuller details were published in the report on the 'Zinc and Lead Deposits of the Upper Mississippi Valley,'² and other papers on the region. It is to be remembered that the region is one that has been studied in much detail and in which mining and geological work have

¹"Types of Ore Deposits," p. 100.

²U. S. Geol. Surv. Bull. 294, pp. 128-129.

*See *Quart. Jour. Geol. Soc.*, Vol. 54, p. 80, 1897.

been conducted for more than a century. It is also driftless and there are excellent rock exposures, so that however much we may differ as to interpretation, there should be no room for differences of opinion as to such fundamental facts as the presence or absence of igneous rocks in the region. While I recognize that evaluation of evidence is largely personal, the facts in this case have seemed to me to be singularly clear and open to but one interpretation; namely, that the ores are sedigenetic in type. Furthermore, it may be asked, why should they be considered 'unique'? To me it is as natural for a deposit of that type to be derived from the action of the agencies that produce sedimentary rocks, as for the veins at Cripple Creek, for example, to be related to a volcano.

If I had had any lingering doubt in the matter it would have been set at rest when I studied the fluor-spar deposits of southern Illinois.³ Here, in the midst of the great Mississippi Valley is a district in which veins are found that are related to igneous rocks, here evidenced by dikes of lamprophyre and mica-peridotites. The veins contain lead and zinc, as do the other and common types of deposit in the Mississippi Valley limestones, but they are different in almost every other particular. They are true veins of fissure type, fluor-spar is the most important gangue mineral, the galena is argentiferous, and in minute detail they resemble the common type of lead vein in the Cordilleran limestones. It is almost as if Nature had set this district in the great valley for the purpose of affording the exception to prove the rule. When one studies the Ozark region it is necessary to admit certain things in the general geology that point to such a possibility as Mr. Thomas suggests, but even here it is distinctly a possibility only, and the deposits link themselves in character with those of Wisconsin, which form one type, rather than with southern Illinois, the other.

The Ozark uplift is a broad, low, elliptical dome. Its northeast-southwest axis is about 300 miles long and the minor axes are perhaps two-thirds as long. The dome rises to 1000 to 1500 ft. above sea-level, roughly 500 to 1000 ft. above the surrounding country, which rises gently to the west. It is clear that no stratum concerned is competent to support such a dome, and careful physiographic studies indicate that it is in fact a warped peneplain, presumably in isostatic equilibrium with the low land around. If so, it must have been bowed up by the influx of material under it at some depth, though, if this be ordinary adjustment in the zone of flowage, the depth is probably too great to permit the influence of the material so transferred to have been felt at the surface. An alternative hypothesis is that there has been an actual introduction of liquid igneous rock under the area and in the skin of the earth: that, in fact, the Ozark uplift is an enormous lacolith. Supporting such a hypothesis is the fact that igneous rocks have in fact found their way clear to the surface, on the south in Arkansas; on the south-

west on Spavinaw creek, Oklahoma; on the east in southern Illinois and western Kentucky; and in the heart of the Ozark country in Camden county, Missouri, where E. M. Shepard some years since found a dike of graphic granite. I do not cite the igneous rocks of southeastern Missouri, which are clearly of pre-Cambrian age, while the dome, and the ore deposits which were formed after it, cannot be older than late Cretaceous, and presumably are of Tertiary age. It is true that the igneous rocks cited are by no means all of the same type, it is not even known that they show consanguinity, as J. P. Iddings has phrased it, nor are their ages certainly known. J. C. Branner was able to determine with fair certainty that some of the Arkansas dikes are of post-Cretaceous age. In Illinois others cut and coke coal beds that belong to the Carboniferous. Since the close of the Cretaceous marked a great change in the region in many particulars, it is at least logical to assume that the rocks were in the main intruded then or shortly after. At any rate the region is one within which igneous agencies were sufficiently active to cause intrusions not far below the surface and not long, geologically speaking, before the ore deposits of the region were formed. So much may fairly be said for Mr. Thomas' hypothesis.

It is one thing, however, to determine a 'might have been' and another to prove a 'was.' When search is made for definite evidence connecting the ores with the supposed igneous rocks it uniformly fails. Unless one start with the fixed hypothesis that there can be no deposits without igneous agencies being active, it is difficult to see how the evidence can be interpreted in favor of an igneo-genetic or igneo-sedigenetic origin of the ores. The deposits in content, character, and every critical detail show kinship to those of Wisconsin and just as certainly show contrast with those of southern Illinois. There is the same practical absence of silver in the galena, total absence of arsenic and antimony, and the same simple gangue of calcite and dolomite, as contrasted with the fluorite and silicified beds of southern Illinois. H. A. Wheeler has found one vein of galena in southeastern Missouri that is argentiferous, but this very fact sets it off as different from the common lead deposit of the region, and my recollection is that the evidence that it is the same age as the others, is decidedly weak.

Mr. Horwood, in his series of articles on the Rand Banket, has given detailed evidence supporting the view that the gold ores of the Rand are intimately related to the intrusive rocks. Mr. Thomas has cited facts of the same sort in connection with the occurrence of the ores of Ontario. Similar evidence is considered ample to connect the southern Illinois veins with other igneous rocks. It would seem but logical to count the failure of such evidence, against any assumption of such a connection in the case of the zinc and lead deposits of Wisconsin and of the Ozarks in general.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Magnesite contains about 52% carbon dioxide.

Coal in the United States yields an average of 7.53 gal. of tar per ton.

If **porphyry copper ore** is exposed to the atmosphere it starts to oxidize.

Eucalyptus oil for flotation purposes costs 14 to 18c. per pound in Australia.

The **graphite** of Pennsylvania is believed generally to be of organic origin.

Crucibles used in melting materials with high melting points are usually made of 3 parts of graphite, 2 parts of clay, 1 part of sand, and smaller amounts of kaolin.

Crushing rolls have an 8% higher output per horsepower hour than does a dry-crushing ball-mill, according to Philip Argall. This advantage is materially lessened when allowance is made for the fact that the ball-mill grinds, elevates, and screens, in one operation.

Winzes or passes should be properly covered when not in use, especially if a staging has been built over them for the purpose of driving a raise. Recently in a Western Australian mine this was being done, the stage collapsed and one man was thrown down a pass and killed.

Bournonite is a lead, copper, antimony sulphide having the composition $(\text{PbCu}_2)_3\text{Sb}_2\text{S}_6$. According to F. R. Van Horn, it occurs abundantly at Park City, Utah, though its presence has been overlooked owing to its similarity to tetrahedrite, which is relatively scarce at Park City.

Speed of the 'runner' of a centrifugal pump must be in definite ratio to the height required to lift the pulp. With an excessive speed and a high peripheral velocity, the scouring effect on lining is so great, and the internal friction so largely increased, that the simple pump is unsuitable for lifts above 25 or 30 feet.

Pipes used for the conveyance of cyanide solution are liable to rapid internal incrustation, and supposed pump troubles are often traceable to this cause. In order that such piping may be easily removed for periodic cleaning, it should be laid, wherever possible, above ground; and every effort should be made to avoid cementing in of pipes in foundations or under concrete flooring.

Extralateral rights under agricultural ground can be claimed by owners of mineral claims outside the land in question, if the mineral claim was located first; not otherwise. In other words, a claimant under agricultural law takes title subject to accrued rights but with this exception he owns all the mineral under his ground. He has no right to follow outside his land any veins or lodes.

The **terrestrial atmosphere** consists of a mixture of gases that may be divided into two distinct classes, namely, (1) the elementary gases such as nitrogen, hydrogen, oxygen, and the gases of the argon group; and (2) the compound gases such as vapor of water, ammonia, ozone, carbonic acid gas, and others. The first group is practically a fixed quantity, but the others vary greatly.

Mica does not enjoy a free market in the United States. The large consumers have their own sources of supply or buy on long-time contract, and there is little general trade. Some sheet mica is bought for export, and clear stock in sizes 2 by 3 inches or larger can be sold to advantage. San Francisco prices range from 75c. to \$1 per pound for the minimum size, depending on the quality of the material.

The **theoretically correct form** for a surface condenser is one having a triangular cross-section, the steam being admitted over one of the sides, and the amount of surface exposed to the steam diminishing in proportion to the decrease in the quantity of steam to be condensed. The air and non-condensable vapors should therefore be taken off at the apex of the triangle opposite the entering steam. In this manner practically all of the tubes will at all times be surrounded by steam and will do approximately an equal amount of work; thus the efficiency of the tube surface as a whole will be increased.

Oil production of California during 1913 was greatly benefited by increased technologic developments, by which the oils were topped and dehydrated with much greater efficiency. These developments included the successful introduction of the Cottrell electric dehydration process. The adoption of the Trumble and Dyer topping and dehydrating processes, and the great advance in methods for obtaining gasoline from natural gas were among the striking achievements of the year; but while less spectacular, the economies effected by many minor improvements in the great refineries at Point Richmond, Oleum, and El Segundo contributed perhaps equally to the general problem of efficient refining. In the United States, according to the U. S. Geological Survey, there was unusual progress in many parts of the country during the year in petroleum refining, especially in the dehydration of heavy crude oils, in obtaining gasoline from natural gas and synthetically from heavy oils, and in obtaining many special products from crude oils.

Special Correspondence

BUTTE, MONTANA

NORTH BUTTE ACQUIRES MORE PROPERTY.—DEVELOPMENT IN THE NEW AREA.—ANACONDA AND GREAT FALLS PLANTS.—COSTS AT BUTTE.—BUTTE & SUPERIOR MILL PRODUCTS.

With the daring characteristic of its president, Thomas F. Cole, the North Butte Mining Co. has recently invested a large sum in the purchase of new mining ground in Butte. Over \$1,500,000 in cash, and 20,000 shares of North Butte stock is to be given for 700 acres of undeveloped mineral ground in the eastern part of the district. If the copper veins in this section can be shown to be similar in value to those on Anaconda hill, the area of Butte's productive copper zone will be greatly increased. The only developments of importance in that area are those of the Bullwhacker Copper Co., and of the Butte & Duluth Mining Co. These mines show a different kind of mineralization from that of Anaconda hill. They are east and west veins, but as a rule are small. The main zone of profitable ore formation strikes north and south along a wide fault zone, with the copper in a disseminated condition, as silicate and sulphide in the adjacent granite. This disseminated mineralization would be called porphyry ore in other copper states. It gives promise of extending over a large area and of being profitable.

An important and significant change is gradually taking place at the reduction works at Anaconda and Great Falls. Anaconda is soon to get all the concentrating ore, and the Great Falls plant will be limited to smelting first-class ore and concentrate. There are several good reasons why Anaconda should get all the concentrating ore. At Great Falls the tailing has never been saved, but is dumped into the Missouri river, there to be irretrievably lost. On this account, Great Falls has paid no attention to re-treatment of tailing, while Anaconda has been developing a leaching process which is a greatly advanced step in the treatment of copper ores. There would be useless expense in building two of these leaching plants with auxiliary sulphuric acid plants, so that the natural result has been the decision to do all the wet concentration at Anaconda. There is also a haulage charge of \$1 per ton from Butte to Great Falls on low-grade ore which is greatly reduced by shipping to Anaconda.

An interesting discussion concerning mining costs at Butte was recently published in *The Butte Miner*. The writer states that the Anaconda Copper Mining Co. spends \$100,000 per day in its operations. Of this, 50% is for labor, 13% for power and fuel, 8.5% for lumber and timber, 7.5% for supplies, 16% for freight, and the balances in taxes, etc. Now that all the concentrating ore is to go to Anaconda, the freight expense will be considerably decreased.

The monthly statements required of the Butte & Superior Copper Co. by the federal court make interesting reading for the metallurgist. Out of 28,758 tons of ore treated in December, 6656 tons of concentrate was recovered by oil flotation. The cost of flotation per ton of concentrate was \$4.56. The concentrate was valued f.o.b. cars, Butte, at \$23.79 per ton. The concentrate assayed 50% zinc, 2.4% lead, 0.5% copper, 1.3% iron, 2.7% manganese, 11% insoluble, 26.3 oz. silver, and 0.05 oz. gold per ton. As the gross value of the merchantable minerals in this product is about \$80 per ton at present prices, it becomes strikingly apparent that the charges and losses beyond the mill are eating up 70% of the value. No wonder that anyone with a reasonable scheme for zinc refining gets a hearing. The Minerals Separation-Hyde case is to be argued on appeal before the Circuit Court at San Francisco February 20.

LONDON

POSSIBILITIES OF MINING IN THE RUSSIAN EMPIRE.—RUSSO-ASIATIC CORPORATION'S ACTIVITIES.—THE RIDDER, SOKOLNI, NERCHINSK SILVER-LEAD-ZINC CONCESSIONS.

Amid the gloom of the London mining market shine the bright rays of the Russian activities of Leslie Urquhart and H. C. Hoover. The Russian Empire has been recognized for some time as a mining field of enormous possibilities, and it is unfortunate, therefore, that many ventures there have been failures. Two factors that make for success have usually been lacking, one being an intimate knowledge of the country, and the other the ability to apply funds to the best advantage on expert advice. In the present combination these factors are present, Mr. Urquhart having lived in Russia practically all his life and knowing the business methods and business opportunities, and Mr. Hoover being endowed with an unusual amount of financial and technological acumen.

----- RAILWAYS. BOUNDARIES.

THE RUSSIAN EMPIRE.

These two gentlemen have made a great success of the Kyshtim copper property, and are now doing the same thing for the Tanalyk, both of these being properties in the South Urals. They have done so much better than most of the English companies operating in Russia that St. Petersburg financiers have been keen to gain their assistance in connection with other properties. They therefore formed the Russo-Asiatic Corporation, 18 months ago, in partnership with Russo-Asiatic Bank, and the Banque du Commerce Privée, and have since had a great number of properties examined. Three concessions have already been obtained in different parts of Siberia, two containing zinc-lead sulphides carrying precious metals, and the other being a coal deposit. The first in order of importance is the Ridder. This concession covers 3000 square miles and is in the southern part of the Altai mountains. Here a silver-lead mine was worked from 1778 to 1863; but operations terminated on the exhaustion of the oxidized ore. It was then found that the foot-wall contained gold, so the oxidized portion was mined by open-cut and treated in primitive stamp-mills until the year 1901. Reliable reports showed that at the time the mine was closed, 98,000 tons of solid

sulphide ore was standing above water-level, averaging 28.5% zinc, 13.5% lead, 1.7% copper, and \$16 gold per ton; together with 110,000 tons of ore requiring concentration, averaging 5.5% lead, 1.2% copper, and \$14.60 gold per ton. In addition, there was 42,000 tons of oxidized ore assaying \$14 gold. In order to test the continuity of the deposit, two bore-holes were put down 250 ft. apart on the strike, and calculated to intersect the lode on the dip, about 200 ft. below the bottom level. Where bore-hole 'A' cut the lode, there was first 23 ft. of solid sulphide assaying 29.2% zinc, 19.1% lead, 2.06% copper, 7.8 oz. silver, and \$17.20 gold per ton. Following this 23 ft., there was 100 ft. of disseminated sulphides, averaging, as far as assayed, 4.5% lead, 8.3% zinc, 1.4 oz. silver, and \$15.20 gold per ton. After this came 122 ft. of gold ore assaying \$11.40 per ton. The second bore-hole gave equally satisfactory results. It may be legitimately assumed that 1,300,000 tons of sulphide ore is in place between the bottom level and the horizon at which the bore-holes cut the lode. The gold ore is not included in this estimate. Another property close by is the Sokolni, which appears to contain similar ore. The development of the Ridder and Sokolni mines, and the concentration and further treatment of the ore, will be in the hands of T. J. Jones, D. P. Mitchell, and R. Gilman Brown.

The Nerchinsk concession covers 8000 square miles. Here also is an old silver-lead-zinc mine, the Kadinsky. The ore is much coarser than that at Ridder, which is similar to that from Broken Hill. The sulphides of zinc and lead can be largely separated by hand, and subsequent water-concentration presents no difficulty. A drilling outfit has been despatched so as to prospect the deposit on the dip. At the Ekibastus coal deposits, which have been examined by Forster Brown & Rees, of Cardiff, there are a large number of seams outcropping. The coal is of Carboniferous age and is of high quality, suitable for household purposes, steam-raising, and coking. Several shafts had been sunk by previous owners, and the Company is now engaged in clearing the deepest workings.

The above is a mere outline intended to give a general idea of the properties and the nature of the business of the Russo-Asiatic. The directors, with exemplary frankness, tell shareholders that some years must elapse before profits will be made, as the deposits have to be tested and developed, metallurgical works erected, and means of communication improved. These will require funds, as well as time. What impresses itself upon the technologist is the extraordinary nature of the Ridder orebody, and he looks forward with unusual interest to the results obtained by development.

MELBOURNE, AUSTRALIA

FIREFLY FIELD.—A TASMANIA PROPOSITION.—AN EXTRAORDINARY PROCEEDING.—STAKING AN AREA BY NIGHT.—SULPHIDE CORROBORATION.

The chief inspector of mines of New South Wales, J. B. Jaquet, has issued a report on the newly discovered Firefly copper field in the Hillgrove district. He expresses himself as "very favorably impressed with the prospects already obtained, and the discovery may lead to the opening of an important new mining field" and further states that, "the true value and extent of the deposit or deposits can only be determined after the expenditure of a considerable amount of capital, and I confidently recommend that the circumstances warrant the required outlay." According to the description he gives of the field, it is difficult of access, but this present disadvantage may ultimately tend to good, since the precipice, which now stands in the way of easy development, may lead to cheap working, by gravity tramways to the river below. Mr. Jaquet states that the field was discovered once before, as far back as 1896, when he found the copper sulphide lode then

worked, to be worth 40% copper and from 10 to 13 oz. silver per ton. Why the locality should have remained untouched till the present time is not easy to understand. Mr. Jaquet's samples of the recent discovery, which is quite distinct from the old one, give from 2 to 12% copper, 13 to 18% lead, and 2 to 14 oz. silver per ton. A galena vein gave 30% zinc, 2% copper, 19% lead, 6% iron, and 7 oz. silver per ton. As the sulphides are found outcropping in places it appears as if the one of oxidation does not extend far below the surface.

The Hercules mine, Tasmania, is once again attracting attention. This is a silver and lead property, with ore estimated to average \$38.40 per ton, but so far the metals have not been extractable. For years the mine has struggled along with little satisfaction to shareholders, and lately an arrangement was made for an amalgamation of the Hercules with the Primrose company, which was operating a mine of similar character. The proposition was to be worked by a company of 300,000 shares, of which the Hercules shareholders were to receive 120,000 and the Primrose shareholders 40,000 shares; 50,000 of the 140,000 shares for the provision of working capital, \$700,000, for the installation of a suitable smelting plant. However, the attempt to raise the requisite money in London has proved a failure. To atone for this failure, experiments made with the treatment of ore by the De Bavay process are understood to have been successful, with the result that Hercules shares, which were naturally unfavorably affected by the failure of the capital-raising scheme, have made a good recovery. Not only has the Hercules large ore reserves, but those in the Primrose are understood to total about 100,000 tons.

The Port Davey Tin Mines, recently formed in Melbourne to exploit certain mineral leases at Cox's Bight, Tasmania, is on the point of liquidation. The chairman, at a recent meeting of the shareholders, had to announce that the claims which A. E. Langford had purchased on behalf of the Company, were not after all the property of the Company, because the vendors had had no title to dispose of. The vendors, when faced with the fact that two of the leases they had sold to the Company were actually held by one Smith, with whom they had had no dealings, maintained that the holder of the leases was a man named Bryant, and that it was from him that they had obtained the option they had passed on to the Company. They were unable to produce any document to show Bryant's ownership; and yet there seems to have been no difficulty in forming the Company. But, most astounding fact of all, the directors resolved to offer the vendors the sum of \$1000 to cancel the contract. That is to say, they are offered \$1000 to cancel an agreement their part of which they are unable to fulfill. Any way the matter is viewed, the directors, Langford, and the vendors are greatly to blame, and it is the innocent shareholders who have to pay, and to pay moreover to those who are to blame perhaps most of all. Even before this debacle was made public, there had been a sensation in connection with the property. An application was made to the Tasmanian mines department for the granting of a lease between two of those held by the above mentioned Smith, the application being made by a man named Cummings, who was acting as an agent for Langford. To this application an objection was entered by Smith on the ground that the claim had not been staked as stated. Cummings asserted that his pegging was done in the dark, without the knowledge of those who were with him. As this necessitated a tramp of four miles over some of the roughest and wildest country in the state, the objector held that the performance was impossible, and as the mining magistrate who heard the case agreed with him, the application was refused. But another interesting question arises out of this: was this central block, which was, or was not, staked in between two blocks supposed to be held by the Port Davey Tin Mines, to be retained by Langford for himself or to be handed over to the Company? The whole affair is not likely to advance the cause of mining.

During the year ended June 30, 1913, the Central mine at Broken Hill produced 211,593 tons of ore, of which 210,440 tons was treated, yielding 32,295 tons of concentrate averaging 67.2% lead, 6.3% zinc, and 33 oz. silver per ton. The flotation plant produced 71,394 tons of zinc concentrate assaying 43.7% zinc, 10.3% lead, and 17.1 oz. silver. The smelter, near Newcastle, treated 53,285 tons of concentrate yielding 13,410 tons lead, 53,642 oz. gold, and 1,112,265 oz. silver. The gold came from custom ores. Ore reserves total 2,352,000 tons. Net

of the rather high-cost producers of copper, but has a vigorous life before it yet.

The fire which destroyed the sampling plant of the First National Copper Co. is another item added to the bad luck which has attended the experimental development of the Hall process at the smelter. This is rather typical, however, for it is rare that a new process does not have to contend with many difficulties which are entirely foreign to the process, but which often serve to condemn it. Word from the plant is that the process itself is giving entirely satisfactory results, but that the operating costs are higher than was at first estimated.

Word from Butte is to the effect that B. B. Thayer, president of the Anaconda Copper Co., has asked the board of directors to authorize the construction of a 2000-ton leaching plant, to use the process devised by Frederick Laist. The plans for the plant have been drawn for some time, but the management has been waiting for the results of further experiment before beginning construction work. The most important point is where to draw the line between wet concentration, followed by smelting, and leaching. The most expensive work in concentration is the regrinding and handling of the fine material, and the coarser the copper-bearing material can be handled the better, so far as the plant required for wet concentration is concerned. However, throwing a larger tonnage on, the leaching plant will require additional capacity there, and the problem

RESIDUE DUMP AT THE CENTRAL MINE, BROKEN HILL, NEW SOUTH WALES.

profits were \$1,340,000, and \$940,000 was paid in dividends. C. F. Courtenay is general manager, James Hebbard mine manager, and P. S. Morse metallurgist.

NEW YORK

UNITED VERDE COPPER CO.'S NEW SUBSIDIARIES.—FIRST NATIONAL PROPERTY.—LEACHING AT BUTTE.—GUGGENHEIM EXPLORATION HOLDINGS.—UTAH COPPER AND NEVADA CONSOLIDATED.

The most interesting news of the week is that the \$3,000,000 United Verde Copper Co. is to be 'unscrambled.' The Company has only two dozen shareholders, being closely controlled by W. A. Clark, its shares are rarely traded in, and but little information about the output or technical operations of the Company are ever given out, it being still in the dark ages in this respect. The newly fledged legislature of Arizona has been displaying its energy by passing some futurist laws on taxation and other subjects. For this and other reasons, the sum of the activities of the United Verde are to be dissociated, and the business which is not directly connected with mining and smelting is to be placed in the hands of four new companies: the Verde Tunnel & Smelter Railroad, \$450,000 capital, to construct and operate the railroad from the mine to the new smelter; Clarkdale Improvement Co., \$1,500,000 capital, to develop the townsite at the new smelter; Upper Verde Farm & Orchard Co., \$175,000, to own and manage the farm and orchard lands; and the United Verde Public Utilities Co., \$250,000, to handle the water, lighting, and sewer systems at Jerome and Clarkdale. The stockholders of the United Verde have been offered the opportunity to subscribe for these shares, pro rata, at par. Mr. Clark took hold of the mine in 1888, and it has since developed into one of the best known mines in the world, having paid over \$30,000,000 in dividends. In its present stage it is one

of the rather high-cost producers of copper, but has a vigorous life before it yet.

The Guggenheim Exploration Co. has issued its annual report, showing a net income of 16.13%, a slight increase over last year. No very important changes in the investments are recorded, except an increase of 33,100 shares of Ray Consolidated stock. The total assets of the Company are given as \$45,000,000, with a surplus of \$24,811,340. It is interesting to notice that the Exploration company does not hold any Braden or Chile Copper Co. stock, in spite of the close relation between the organizations. The Braden continues to show an increase in its output and is now producing at the highest rate in its history. The Utah Copper has given out its report for the fourth quarter of 1913, showing an output of 23,884,467 lb. copper at an average cost of 9.987c. per pound. The average assay of the ore milled was 1.2165% copper, 2,113,080 tons having been milled during the quarter, of which 56% was treated by the Magna plant and 44% by the Arthur. The stock of unsold copper on hand December 31, 1913, was 39,854,993 lb. The amount of stripping removed during the year was 4,835,489 cu. yd. E. A. Wall has filed suit for \$12,000,000 damages against the Company, asking \$2,000,000 for the surface rights to his properties which have been covered by waste, and \$10,000,000 for the claims which have been buried under waste. The Utah company would feel lonesome if Mr. Wall were not tilting against it, however. The Nevada Consolidated, in its report for the fourth quarter, shows a decrease in operating cost, having produced 16,684,955 lb. copper at a cost of 8.63c. per pound, from 833,989 tons of ore averaging 1.53% copper. The Company has on hand 27,916,946 lb. copper. Of stripping, 982,689 tons was removed at a cost of \$308,519, of which \$171,272 was charged to operating cost and the rest deferred.

LEAD, SOUTH DAKOTA

NEW EQUIPMENT AT THE HOMESTAKE.—WASP NO. 2.—A MILD WINTER IN THE BLACK HILLS.—THE MINNESOTA, GOLDEN CREST, TITANIC, AND HIDDEN TREASURE.—OIL AT ARDMORE.

Extensive plans for improvements have been arranged by the Homestake Mining Co., expenditures for which during the present year will probably total \$350,000. Among these will be a plant containing six 600-hp. boilers, equipped with superheaters. The site chosen is close to the Northwestern railway, where good facilities are offered for delivery of fuel. Experiments will be made with oil fuel. Should this fuel be adopted it will be the first application in the Black Hills mines. Steam from this plant will be used to operate an electric-generating station and a new hoisting engine at the B. & M., formerly known as the Old Abe shaft. The electric plant will be used as an auxiliary to the Spearfish hydro-electric station. It will have a normal capacity of 3200 and a maximum, for short periods, of 4800 hp. The new hoisting engine will have a capacity of 3000 ft., and will be the best on the property. Contracts have been let for this machine, and delivery will shortly commence; and it is hoped to have it in operation before the end of the current year. The shaft is now 1500 ft. deep, has five compartments, and is equipped with a complete electrically driven pumping system. The new engine will make it one of the most important ore-hoisting shafts on the property. The machinery for the three plants mentioned will cost about as follows: boiler plant, \$100,000; electric station, \$45,000; and hoist, \$75,000. In addition the buildings will cost about \$130,000.

The Wasp No. 2 is working practically at normal capacity, producing nearly 500 tons of ore per day. John Gray has resigned as general manager, his health necessitating the action, and he has been succeeded by Edward Manion, one of the best known mining men in the Black Hills. C. E. Brenner, for several years mill superintendent, has also resigned on account of poor health, and Ray Craig is in charge of the plant.

Salubrious weather has marked the winter season in the Black Hills. Up to January 20 the snowfall at Deadwood had been only 5 in. for the season, with none lying on the ground at that time. The coldest night reported was 2° below zero. Many nights in December and January were recorded when the thermometer was well above the freezing point. This weather has been of great benefit to the mining industry, permitting of outdoor and construction operations on a scale greater than for years past. At the Wasp No. 2, Bismarck, Homestake, and other properties, where considerable open-cut mining is done, conditions have been ideal for the work. At the Mogul and Rattlesnake Jack, construction on the mills and about the mines has been pushed almost as during the summer. Other properties report greater activities than would have been possible under adverse conditions; and all operators are praying for a mild winter.

Dewatering the 200-ft. shaft of the Minnesota property, at Maitland, is proceeding under the direction of Joseph Kellar. At the 70-ft. level a connection is made, by adit, with the surface, and the 100-ft. level is above water, where the ore was followed upward on the dip. The 200-ft. level contains extensive workings and will require some little time to drain. Preparations are being made to start further development as soon as the water is removed.

F. W. Bird and associates have secured title to the Golden Crest property, in the Galena district, and state that the property will be in full operation in a few months. The title was secured upon judgment for \$120,000, against the Detroit interests in the Company, who failed to redeem within the time granted by law. Litigation started about the time the mill was completed, and as a result the plant, which contains 40 stamps, and is one of the most modern and thoroughly

equipped in the Black Hills, has never turned a wheel. Bird and associates have done some development, and report having uncovered a large body of ore at the surface, which, while low in grade, they state will pay if handled in large quantities by steam-shovel mining methods. On the lower levels are some bodies of good grade milling ore.

Sinking is going on rapidly at the Titanic property, at Carbonate, the shaft now being 190 ft. deep. It is the present intention to go to 300 ft. before further cross-cutting is undertaken. Ingersoll-Rand jackhammer drills are being used in sinking, and are giving good results.

Encouraged by the results of work done in an adit west of the shaft last summer, the Hidden Treasure company, owning property on upper Deadwood gulch, has decided to sink the shaft an additional 200 ft., and at that depth do some lateral

DRILLING FOR ORE AT ARDMORE, SOUTH DAKOTA.

work. The property is equipped with a gasoline-driven hoist and compressor, air drills, pumps, etc. Banks Stewart, of Deadwood, is general manager for the Company.

The Continental Copper Co., near Hill City, has just completed the installation of a big Goulds Manufacturing Co.'s electrically driven triplex pump on the 700-ft. level. The machine, complete, weighed 23,000 lb., and was put in place with little difficulty. The shaft is 800 ft. deep, is to be sunk 200 ft. farther, and the pump will later be removed to the 1000-ft. level.

Well No. 1 of the Ardmore Oil Co., at Ardmore, was 1100 ft. deep on January 19. Progress lately has been rather slow, owing to encountering some hard strata dipping to the southeast, which deflected the drill. The hole is still being carried down with a diameter of 12½ in. It is expected that the Dakota sandstone, the most likely formation for containing oil, will be cut at a depth of about 1700 feet.

JOPLIN, MISSOURI

ZINC AND LEAD PRICES.—DRAINAGE OF A FAMOUS OLD DISTRICT.—RUSH FOR LEASES TO NEW SHALLOW-MINING DISTRICT.—GEOLOGICAL WORK.—NEW MILLS.—PUMPING AND DRILLING WORK.

The zinc and lead ore markets are stronger than they have been for several weeks, producers of both ores finding a ready demand at fair prices. The large tonnage of spelter on hand at the various smelters has a tendency to lessen the demand for ore. However, as the smelters are reported to be operating at about 75% capacity, they are in the market for about 5000 tons of zinc sulphide ores per week at prices ranging from \$40 to \$43, basis of 60% metallic zinc, while

the higher grades bring as high as \$46 per ton. Spelter at East St. Louis is quoted at \$5.20 per 100 lb. In the corresponding week of 1913, blende brought \$44 to \$48, basis, with choicer grades selling for as high as \$51. Spelter was then quoted at \$6.40. Calamine is selling for \$20 to \$22, basis of 40% metallic zinc, with top grades bringing up to \$26. Lead ore brings \$50, and pig lead at East St. Louis is quoted at \$4.05. In the corresponding week of 1913, calamine brought \$24 to \$26, basis, with top grades selling for \$30. Lead ore brought \$53, basis of 80% metallic lead, and pig lead was quoted at \$4.225. Despite the apparent strength of the market a year ago compared with the offerings of today, the demand at that time was on the decline and prices were dropping steadily. In a single week's time zinc sulphide ores had dropped from \$54 to \$56, basis, to \$44 to \$48, basis.

Prior to pumping operations, which have been started in Lone Elm 'bottoms,' this old mining region remained virtually idle for about 15 years. The Schoenherr Development Co. has acquired leases on the Granby Mining & Smelting Co.'s land, and the Picher Lead Co.'s land, the property being situated in a long valley, in the northwest portion of the city of Joplin. It was once the scene of many rich finds, both zinc and lead sulphides being produced. As the residential portion of Joplin gradually extended northward, it was found that the constant pumping in Lone Elm caused more or less inconvenience to property owners in the residence districts, as the removal of water from old drifts of mines worked in the early days caused several cave-ins. As much of the north part of the city thus effected was in danger, pressure was brought to bear against the operators in Lone Elm and work was stopped. Several years ago pumping was again started, and as a result the ground beneath the beautiful Congregational church, constructed of sandstone, gave way and the church had to be removed to another property. One big residence, in an exclusive residence portion, narrowly missed being swallowed by a gaping cave-in that opened over night beneath its foundations. Numerous other smaller cave-ins occurred. Again pumping operations were stopped. The present Company has progressed with success and no cave-ins of importance have been reported, although the water has now been lowered to a depth of 125 ft. The richest bodies of ore occur at 100 to 120 ft., and as the ground has been cut to a limited extent, a heavy production of concentrate can be expected from this area. Plans are already on foot for the construction of several large concentrating plants.

A tent city has sprung up in the Cedar Creek district, 10 miles south of Joplin, and scores of prospectors are flocking to a region where recent discoveries of calamine and carbonate of lead have been made from shallow levels down to 70 ft. At some places the ore is found in outcrops, and prospectors are clearing from \$50 to \$150 per week each in cleaning these low-grade products for the markets. The bulk of the work is being done on the McAntire farm, the Butts property, and the German-American Mining Co.'s land. On the Scherl farm, 1½ miles distant from this field, lead and calamine have been discovered at shallow levels in drilling, while in deeper prospecting good zincblende is shown. Along Cedar creek, which, prior to a few months ago, traversed a remarkably secluded country in which little mining was undertaken, more than a dozen wash places have been started, while many other prospectors are selling only their 'chunk' ore and are keeping their fine 'dirt' for future cleaning. The mines of this immediate vicinity are now figuring conspicuously in the weekly production of ore, and a still larger increase may be looked for.

The Missouri Geological Survey plans to establish offices in Joplin with the view to getting more detailed information on mining conditions. The Survey is trying to work in co-operation with mining men and prospectors, and is meeting with encouragement from some of the larger companies. The

plan is to keep complete drill records from as many portions of the district as possible, and also gather other information concerning geological formations, mining practice, and so forth. The importance of a knowledge of geology in relation to zinc and lead development is beginning to be more greatly appreciated than ever before, especially by the old-timers, who formerly were wont to scoff at anything that hinted of scientific methods in mining.

Two large new concentrating plants in the West Joplin field will begin operations in the near future. One is the Arco Mining Co., equipped with a large mill of 200 tons daily capacity, situated on the Connor land at Central City, due west of Joplin. The other is that of the Dundas Mining Co., situated on the Connor land at Chitwood, northwest of Joplin. In the latter mine some of the highest grade zinc-blende found in the district is mined, assays having shown the concentrate to carry as high as 64% metallic zinc.

Work is now well under way at the Lennan mine, North Miami, Oklahoma, where pumps are draining the ground to a depth of 320 ft. This is the deepest work in the entire Missouri-Kansas-Oklahoma district, and one of the largest pumping plants in the district is employed. The deep ground contains lead ore that is exceptionally high grade, as much as 84% metal, and thus commanding \$4 per ton above the ordinary basis settlement paid for 80% ore.

The Co-operative Prospecting Co., a subsidiary company of W. M. Sheridan & Co., has recently acquired a lease on the Schifferdecker land in West Joplin, and has begun drilling operations on the tract formerly mined by the Alice of Old Vincennes Lead & Zinc Co., and later by the Abigail Mining Co., both of which companies operated large concentrating plants. In addition to this lease, the Co-operative company has been developing tracts in various other portions of the district. Following this prospecting work, which has resulted in two or three encouraging properties being opened, new concentrating plants will be erected in the near future by companies which have taken subleases on the lands thus prospected.

PEARCE, ARIZONA

COMMONWEALTH MINE AND MILL.—THE PEARCE DISTRICT.—COMMONWEALTH EXTENSION.

The recently completed stamp-mill at the Commonwealth mine is at present treating from 275 to 300 tons per day, and improvements are contemplated to increase the capacity and improve the results at present being obtained. Betterments include increased tube-mill capacity and the perfection of minor details in the mechanical handling of the mill production. Diaphragm pumps are being substituted for the air-lifts on the Dorr thickener discharge, and screw feeds are to be substituted for the present spiral feeds of the tube-mills. The Oliver filter-plant has recently been overhauled and satisfactory results are being obtained from this department. The mine is in good condition, and a large tonnage of ore is at present developed and in the stopes ready for extraction by the shrinkage method of mining, which is being employed. The one-man drill is being used entirely and with excellent results. The present workings extend only to a depth of 350 ft., and ore is being mined through an inclined shaft and hoisted by means of 3-ton skips. The present development is entirely in the oxidized zone, and the indications are that the sulphides will not be found until great depth is attained.

A number of prospects are being developed in the Pearce district and some with a great deal of promise. Active operations will be commenced on the Commonwealth Extension soon. At the Johnson property development work has opened a good sized orebody and shipments are being made, the company at present employing ten wagon teams for transporting ore from the mine to Cochise for shipment.

General Mining News

ALASKA

FAIRBANKS

The underground dredge, owned by the Tanana Mines Excavation & Manufacturing Co., is to be tested in some ground at the lower end of Fairbanks creek. The gravel here is about 65 ft. to bedrock, and the machine will be erected at the shaft bottom. It is hoped to reduce mining costs by 66% with the apparatus, although on Cleary creek it did not work satisfactorily, the ground being very hard. John Beck, the designer and maker, is in charge.

VALDEZ

For the construction of a wharf and ore-bins at the foot of Solomon gulch, the Granby company of British Columbia, which owns the Midas mine in Solomon basin, is calling for bids for 38,000 ft. of piling. It is expected that over 300 men will be employed on the property during the summer.

Development at the Nelchina district is promising, and there are 250 men and 3 women in camp, according to Angus McDougall, of Fairbanks. He has ordered a 5-in. Empire drill to prospect the wet ground on his claims. Griffith brothers have an option on three claims on Crooked creek for \$9000. A 9-in. drill is working. A new discovery of good gravel is reported from Dublin gulch, 18 miles from Crooked creek. Bedrock on Shovel creek was 40 ft. deep. From Crooked creek to Copper Center takes two days, and from there to Valdez, another four days, over good trails.

ARIZONA

A bill is to be discussed before the state legislature at Phoenix, concerning the non-employment in mines of any person who does not understand the English language. Petitions from Gila county contain enough names to place the measure before the voters at the election next November.

COCHISE COUNTY

On February 2, the Calumet & Arizona smelter beat all previous records, for the old and new plants, by treating 400 tons of ore and 250 tons of converter products, the metal output for the day being 324,000 lb. of copper. The new smelter consists of receiving bins, a 200-ton per hour crushing and sampling plant, an ore bedding and conveyor system with a holding capacity of 60,000 tons, a roasting plant of twelve 21½-ft. Herreshoff furnaces, two 40 by 48-in. blast-furnaces, four 19 by 100-ft. reverberatory furnaces, and Great Falls type of converters.

GILA COUNTY

The Ray company, at its mill at Hayden, has just completed the construction of a long flume to carry tailing from the mill to more available ground. The company owns the entire valley land from Hayden Junction to Winkelman, a distance of about four miles, which is being used for depositing the tailing. The old system of allowing it to run down through cañons is now being replaced by the system of flumes so that the tailing can be carried farther away and allow the land there to be covered up and then filling up gradually back toward the mills. The plant is treating 8000 tons of ore per day.

(Special Correspondence.)—About 7000 ft. of development was done in the Inspiration mine in January, and 9000 tons of ore was sent to the flotation plant. Connection between the Colorado and Incline shaft, at 600 ft., should be made within 60 days. This will aid work on the Colorado orebody. On account of a slide in the Geneva railroad cut, between the millsite and the Inspiration camp, the test mill was shut down until the debris was cleared away. Practically

all steel is in place for the crushing plant, and riveting will soon be started. Grading for the smelter site is finished.

Miami, February 7.

(Special Correspondence.)—The Iron Cap mine shipped 16 cars of ore in January. A night shift is now employed, and the country on the 800-ft. level westward along the main vein is to be prospected. About 500 ft. west of the shaft the vein has been faulted, and what is known as the cross-faulted area is to be explored. Good progress is being made on the 1300 and 1400-ft. levels of the Arizona Commercial, and within 30 days the vein should be cut on the latter level. Water at 1200 ft. is the reason that the two lower levels, which are dry, are being opened first. At the Superior & Boston, the vein has been reached by the cross-cut on the 1000-ft. level. Lessees are busy mining ore from three different areas of the mine.

Globe, February 7.

GREENLEE COUNTY

Five per cent copper ore has been opened in the claims of the Keating Copper Syndicate, near Metcalf. At a depth of 250 ft. the vein is 18 ft. wide. Two shafts have been sunk and drifts driven from them. English capital is interested in the property.

PINAL COUNTY

An unaccountable explosion at the Carney mine, near Ray, destroyed the machinery and a house on February 3. Nobody was injured. There has been a bad feeling among the miners of the district of late, and this explosion is supposed to be due to that.

MOHAVE COUNTY

Litigation concerning the Frisco Gold Mines Co.'s property has been settled, and the superintendent, James A. Roberts, has recommended the erection of a 500-ton mill. An air-compressor, pumps, and drills are being installed at the Telluride mine, at Oatman. The 200-ft. level is opening well.

MARICOPA COUNTY

A bond has been secured on the old Vulture tailing dump, 16 miles below Wickenburg, on the Hassayampa river, by M. B. Lauzon, John Perry, and J. F. Powell. The tailing contains from \$1 to \$5 per ton, and probably a 100-ton cyanide plant will be erected.

SANTA CRUZ COUNTY

The World's Fair mine was valued at \$155,000 by the tax commission of the state of Arizona, and \$7000 was collected in taxes. Frank and Josephine Powers questioned the validity of the mine tax law, but have been defeated in two courts.

YAVAPAI COUNTY

Mining in the Walker district is quite encouraging at present. The Lambertine and Eureka mines are opening good ore-shoots. A head-frame, hoist, and pump are being installed at the Poorman.

CALIFORNIA

California mine operators desiring to take out working-men's compensation insurance with the state, can obtain blank forms and full particulars from the treasurer or the clerk of any city, town, or county in the state.

INYO COUNTY

Lessees at the Cerro Gordo mine, at Keeler, have opened a large orebody on the 700-ft. level. A drift is being driven at 200 ft. to cut this shoot. About 25 tons of ore containing 110 to 125 oz. silver, 10% lead, and \$1 gold is being shipped daily. Zinc ore is not being shipped, pending development of the new orebody. Thirty men are employed.

PLACER COUNTY

The dredge of the Eldorado & Placer Counties Gold Mining & Power Co. is ready for work, this making the third boat on the middle fork of the American river. This Company will dredge the river from Poverty flat to Oregon bar,

a distance of two miles. Keystone drill tests show the gravel to contain good gold content. Just below this point, the Pacific Gold Dredging Co.'s boat is working on the Mammoth bar.

SAN BERNARDINO COUNTY

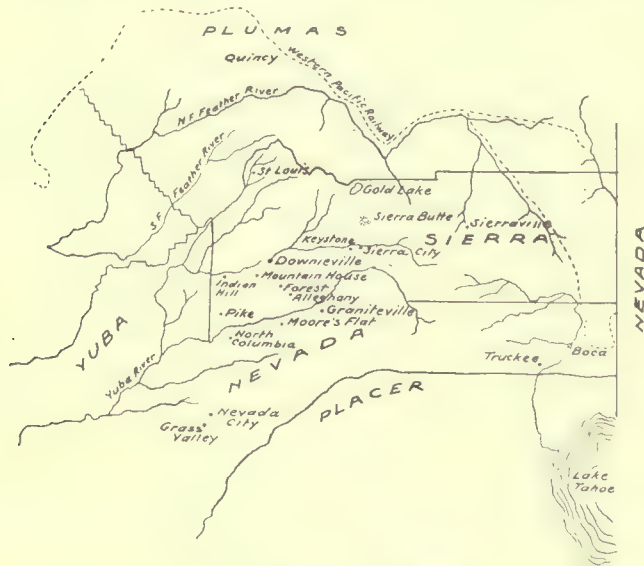

Production of potash from Searles Lake is now expected to begin in April, by which time the American Trona Co. anticipates having the first unit of its plant in operation. This will be a small pilot plant, of about 1% of the capacity of the main works. It will be used to determine the proper slope of the dryers and similar facts necessary to large-scale economical working. The Trona railroad has been graded to the works and about 20 miles of rails are laid. Part of the new town of Trona has been built and material is being rapidly delivered. To haul in machinery and supplies, auto-trucks are employed to supplement mule-trains. In part, the work is by contract, \$8.33 per ton over 27 miles of desert road, and in part a big Peerless truck belonging to the Company is employed. A Renard locomotive, hauling a train of small cars, is also used. This engine runs on heavy steel wheels at the rear, but has ordinary rubber-tired auto wheels in front. About 20 tons per load is hauled, and satisfactory service has been maintained for more than a year.

SHASTA COUNTY

Experiments are to be conducted at the Noble electric smelter, at Heroult, by R. C. Palmer and C. S. Smith, of the Forest Service, to see what can be done in the way of producing by-products from the distillation of California woods. In the meantime the smelter has been temporarily shut down during the changing of graphite for carbon electrodes. Since early in December about 3000 tons of iron has been made.

SIERRA COUNTY

There are 600 men working for wages in the gold district of Sierra county this winter. About 150 of these are em-

MAP OF SIERRA COUNTY.

ployed about Alleghany, followed by Sierra City, Pike, Forest City, Downieville, Howland Flat, Scales, and Brand City. By July 1, at least 1000 men are expected to be at work underground. Two shifts are working in the Claybank mine near La Borte. The old adit, 6500 ft. long, is being repaired and will be used for drainage. Both the Sixteen-to-One and Occidental mines, near Alleghany, are developing satisfactorily.

SISKIYOU COUNTY

The Sugar Pine hydraulic mine, in Selad valley, near the

Klamath river, is working full time. Water is secured from Selad creek, and goes to the monitors through 5½ miles of flume, and a half-mile of 11 to 20-in. steel pipe. P. R. Kelsey is manager. In the Forks of Salmon district, hydraulic elevators are busy at the Michigan Salmon, Forks of Salmon, Bennett, and other gravel properties. A soft quartz vein formation is being sluiced on the Noonung, estate on the Scott river. Rich pockets of gold are occasionally found. There is plenty of water for hydraulic mining in the county.

TRINITY COUNTY

The Lagrange company's siphon has been repaired, and hydraulicking is being done day and night. It is said that gold returns will amount to \$1000 per day. Water is in abundance.

TUOLUMNE COUNTY

Work is to be started at once at the Corbin mine, near Jamestown, and the shaft will be sunk 200 ft. Jesse P. Mangante is superintendent of the Jamestown Exploration Co., which owns the property.

COLORADO

LAKE COUNTY (LEADVILLE)

The tonnage of ore from the Yak tunnel during January was up to the average. Zinc sulphide is being shipped from the White Cap stopes, and some high-grade silver ore from the lower levels of this mine. A large tonnage is being mined from the Cord. From the Vega and Diamond ground, at the breast of the tunnel, some lead ore is shipped. Sulphide ore, containing silver and lead, is being extracted from the Louisville, Iron hill, and is sent out through the Yak tunnel.

TELLER COUNTY (CRIPPLE CREEK)

January gold yields from the district mines are estimated as follows:

| Plant and location. | Tonnage. | Val per ton. | Gross val. |
|----------------------------------|----------|--------------|-------------|
| Golden Cycle, Colorado Springs. | 36,600 | \$20.00 | \$ 732,000 |
| Portland, Colorado Springs. | 10,000 | 20.00 | 200,000 |
| Smelters, Denver and Pueblo... | 4,300 | 55.00 | 236,500 |
| Cripple Creek: | | | |
| Portland | 15,500 | 3.00 | 46,500 |
| Stratton's Independence | 9,963 | 2.96 | 29,490 |
| Colburn-Ajax | 4,800 | 5.50 | 26,400 |
| Kavanagh-Jo Dandy | 1,700 | 2.15 | 3,655 |
| Wild Horse | 1,200 | 3.68 | 4,416 |
| Gaylord-Dante | 1,100 | 3.50 | 3,650 |
| Isabella mines | 750 | 3.00 | 2,250 |
| Rex M. & M. Co..... | 300 | 2.25 | 675 |
| Total | 86,213 | | \$1,285,536 |

Dividends totaled \$176,185, paid by the Golden Cycle, Portland, Vindicator, and Mary McKinney companies. Over 4000 tons of ore was shipped from the Elkton mines during the month.

During January the Vindicator produced nearly 3000 tons of ore, of which 1800 tons of \$30.75 ore was mined by the company.

Four feet of rich ore is being opened at 400 ft. in the Ajax estate, Block 13, and returns from two carloads were \$40 and \$70 per ton, respectively. B. Colburn is superintendent. The flow of water from the Roosevelt drainage tunnel is 7480 gal. per minute, an increase over recent measurements.

IDAHO

ELMORE COUNTY

(Special Correspondence.)—The Overlook Mining & Development Co. is operating gold-bearing claims near Atlanta. About 3500 ft. of underground work has been done to a depth of about 700 ft. The property is being thoroughly developed before installing a plant. During next summer a

3-stamp Joshua Hendy mill, with quadruple discharge, will be used for testing the ore. Neil Campbell is general manager. Atlanta, January 28.

NEZ PERCE COUNTY

(Special Correspondence.)—A cyanide plant is to be erected at the Jumbo mine, near Lewiston, in the spring. Mr. Baerlocher is manager of the Jumbo Mining & Milling Company. Greencreek, January 26.

SHOSHONE COUNTY

There are two parallel veins in the Interstate-Callahan mine; one contains lead and silver, and the other zinc with a little lead. The zinc lode has now been opened for 800 ft., showing 8 to 12 ft. of shipping ore, but in places it is from 20 to 40 ft. wide. The mill is working at full capacity producing clean lead and zinc concentrates. A cross-cut in the Virginia has cut the vein. During January the Stewart Mining Co.'s net earnings were \$78,000, against \$22,000 for the same month of 1913.

The annual meeting of the Tamarack & Custer Consolidated Mining Co. was held at Wallace on January 28. Nothing of importance transpired. Ore shipped in 1913 was worth \$366,071. The cash reserve is \$64,610, and ore and concentrate worth \$20,000 is in transit to the smelter. Improvements cost \$57,000, and \$40,000 of indebtedness has been liquidated. Jerome J. Day is general manager.

Ore and concentrate shipments from 15 Coeur d'Alene district mines in January totaled 41,000 tons. The Marsh mine is now treating 150 tons of ore per day.

MISSOURI

JASPER COUNTY

According to the annual issue of the *Joplin News Herald*, the value of zinc and lead ores from the Missouri-Kansas-Oklahoma district from 1830 to 1913, inclusive, was \$255,530,078. Of this, approximately \$150,000,000 is the production of the last 10 years, that of 1913 being \$14,356,461.

ST. FRANCOIS COUNTY

(Special Correspondence.)—Litigation over the St. Joe-Doe Run lead companies is evidently not to be immediately ended. On January 29, Justice Cardozo of the New York Supreme Court dismissed the action of Robert Holmes, who sought to restrain the St. Joseph Lead Co. from borrowing \$2,500,000 from White Weld & Co., and Smith Moore & Co., and at the same time paying a 4% dividend. Holmes contended that the price paid for the loan was excessive and that if the dividend were not paid it would be unnecessary to borrow. The court held that the directors had not exceeded their authority in contracting for the loan, but declined to pass upon the point whether the directors might not be enjoined from paying a dividend. Mr. Holmes declares that he will carry the fight further and states that with the exception of one or two departments the business of the companies is being poorly conducted, principally because there is no resident head. At the recent stockholders meeting Mr. Holmes and his friends voted 30% of the stock.

St. Louis, January 31.

MONTANA

Seventeen 3.25 and 4-ton locomotives have been ordered by the Anaconda Copper Mining Co. from the Westinghouse Electric & Manufacturing Co. for underground haulage in its various mines. The mining company has in the past preferred the standard steel-plate construction of locomotive, sometimes referred to as the armor-plate design. However, about a year and a half ago one of the subsidiary companies purchased, somewhat in the nature of an experiment, three open-frame bar-steel locomotives. These locomotives have been in constant service ever since they were installed, not requiring any mechanical or electrical repairs with the exception of the renewal of the brake shoes. On the strength of this

performance, the Anaconda company decided last summer to purchase five 4-ton bar-steel frame locomotives with commutating-pole motor equipment for certain surface haulage. The operators found this type of construction so satisfactory that it was specified on the order mentioned. Each locomotive will be equipped with two 11-hp. commutating-pole motors, representing the latest advance in mining locomotives for narrow-gauge haulage.

NEVADA

The new Nevada Safety Commission, appointed on February 6, to continue the work of the Safety First Conference held at Reno during the last week of January, consists of the following members: Tasker L. Oddie, governor of the state; L. L. Ricketts, editor of the *Reno Gazette and Goldfield News*; W. B. Alexander, secretary of the Mine Operators' Association; G. A. Bartlett, ex-congressman and attorney general for the Pacific Power Co.; H. A. Lemmon, industrial agent for Truckee River General Electric Co.; W. E. Wallace, legislative agent for the Brotherhood of Railroad Trainmen; E. Ryan, state mine inspector; J. J. Mullen, secretary of the State Industrial Commission; and J. G. Scrugham, professor of electrical engineering at the University of Nevada. The formation of this commission was suggested by Mr. Mullen on the last day of the Safety First Conference.

ESMERALDA COUNTY

An air-compressor of four 2¼-in. machine-drill capacity has been ordered for the Silver Pick mine. At the 500-ft. level a triplex 5 by 12 in. electrically driven pump of 200 gal. capacity is to be installed. Walter S. Norris is superintendent. A drift has been started in the incline raise, above the 359-ft. level of the Florence, to determine the extent of the rich shoot. Ore on the 500-ft. level of the Sandstorm-Kendall maintains its value. The pump is working well, as is also a new air-compressor. Development in the Vernal is encouraging. The Jumbo Extension shipped 1183 tons of ore in December worth \$12,322. The Bonne Claire mill treated 1080 tons, yielding 83 tons of concentrate worth \$10,766 net. The month's profit was \$11,058. A system of reconcentration is being tried in the mill. This involves pumping the concentrate, after it has passed from the lower tier of tables, to the upper Deister tables below the second batteries.

MINERAL COUNTY

At the bottom of a shaft in old workings of the Aurora mine, which have been unwatered, there is an 8-in. vein assaying from \$700 to \$3125 in gold per ton.

NYE COUNTY

The Tonopah Extension Mining Co. reports that the December output was \$34,694, and current expenses \$42,753. A large amount of development is being done, and the grade of ore treated in January showed an improvement. The mines at Tonopah produced 11,563 tons of ore worth \$276,370 during the week ended February 7. The Tonopah Mining Co. has taken an option on a property in Nicaragua. At the annual meeting of the Manhattan White Caps Co., the proposed amalgamation of this company, the Associated Milling, and White Caps Leasing companies was discussed, and it was decided to have a valuation made of the respective properties for this end. John G. Kirchen stated that the White Caps refractory ores can be treated.

WHITE PINE COUNTY

The State Railroad Commission has ordered reductions in freight rates on black powder, pig iron, and ore and concentrates carried by the Nevada Northern railroad. The reductions amount to 7c. per cwt., 19.5c. per cwt., and from \$1 to \$3.50 per ton respectively.

NEW MEXICO

SOCORRO COUNTY

A new orebody, assaying \$17 to \$25 per ton, has been opened

below adit 'C' in the east end tunnel group of the Oaks Company. A drift has been driven 60 ft. into a shoot recently cut in the Precious Metals Mining Co.'s ground. This is the first important discovery in the south part of the Mogollon district.

SIERRA COUNTY

An old mining camp 13 miles north of Grafton, on the south boundary of Socorro county, has been named Calumet. Some of the mines are in that county. In the early eighties the camps at St. Charles, Phillipsburg, and Fluorine were known as Grafton. Calumet takes the place of Phillipsburg. The Calumet Commercial Co. has bought 21, and secured a lease and bond on 7 other claims. About 60 men are employed according to W. B. Duvall, general manager. Rich gold and silver ore has been opened in the great Republic, and the Occidental shaft has cut \$12 ore. The old Phillips cyanide plant is being overhauled, and capacity increased to 100 tons per day.

NORTH CAROLINA

UNION COUNTY

(Special Correspondence.)—The Howie Mining Co. is operating a mine and mill at Waxhaw. The main shaft is down 365 ft., and will probably be sunk deeper. Rich gold ore has recently been opened, and the mill is treating 25 tons per day of \$10 to \$40 ore at present. Robert Clarke is general manager.

Waxhaw, January 25.

UTAH

BEAVER COUNTY

Mining in this county is attracting considerable attention, and ore shipments are greater than ever before. Two shifts are working at the Hoosier Boy, and there is a good tonnage of silver-lead ore at 200 ft. The shaft is being sunk to 400 ft. A. D. Moffatt is manager of this well equipped property. Twelve miles southwest of Milford, and near the Hoosier Boy, is the Moscow, in charge of Garret Wilkin. Fifty men are employed mining high-grade carbonate of lead, and sinking a two-compartment shaft to 1000 ft. The Red Warrior is raising good ore from between the 500 and 600-ft. levels. A bond and lease has been secured on the Cave mine, 7 miles east of Milford, and ore is being mined. J. M. Reynolds, of Milford, states that the outlook is excellent.

JUAB COUNTY

Ore shipments from 18 mines in the Tintic district during the past week totaled 153 cars.

PIUTE COUNTY

Gold-bearing ore worth \$9 per ton has been opened by the Beaver Mines Co., near Marysville, in an adit 540 ft. long and at a depth of 225 feet.

SALT LAKE COUNTY

As a sequel to a suit filed four years ago by the Bingham & Garfield railway against Enos A. and Mary F. Wall to condemn right of way across valuable mining property in Bingham cañon for the company's road, Colonel Wall and his wife have filed in the district court an answer and cross-claim demanding damages from the railroad of \$12,005,000. The charge states that the railway is not an individual corporation, but only a part of the Utah Copper Co., and cannot exercise eminent domain in its own right; the railway also covered ores of the plaintiff; the surface value of the lands involved have been destroyed for mining purposes; and that the railway has made the mining of ores, in a similar manner to that of the Utah Copper Co., an impossibility.

SUMMIT COUNTY

On the 1550-ft. level of the Silver King Consolidated, the west drift has opened 23 ft. of first-class galena ore. During 8 months of the past year, the American Flag mine shipped

746 tons of ore worth \$40,558 to the Murray smelter. This ore came from the Easter vein.

WASHINGTON

The annual report of the Washington Water Power Co. gives the following information:

| | |
|---|-------------|
| Consumers of electric current in Washington and Idaho | 22,640 |
| Output of current, kilowatt-hours | 157,061,662 |
| Gross receipts | \$2,909,147 |
| Total expenses | 1,291,673 |
| Net earnings | 1,109,191 |
| Spent on Long Lake project | 1,012,030 |

There was an increase in business of 16.1%. The properties of the Idaho-Washington Light & Power Co., and the Big

TRANSMISSION LINES OF THE WASHINGTON WATER POWER CO.

Bend Light & Power Co. were acquired during the year. An examination of the Republic mining district, Ferry county, failed to justify the construction of a transmission line.

FERRY COUNTY

There is some activity in the Orient mining district, and claims are being sold and optioned.

SPOKANE COUNTY

During January the Spokane Stock Exchange traded in a total of 65,018 shares worth \$44,858. The greatest number of shares was 14,000 in the Benton and 10,000 in the Idora Hill, while the highest value was \$27,093 in Granby Consolidated, and \$2977 in Caledonia.

CANADA

BRITISH COLUMBIA

The Van-Roi mine at Silverton produced 1962 tons of ore in December, averaging 9.7 oz. silver, 1.8% lead, and 8.4% zinc. The mill products were worth \$7126, and total costs were \$8292. Developments are encouraging. The old Nickel Plate mine, which has been shut down for about 10 years, will probably be reopened.

ONTARIO

During 1913 the Crown Reserve Mining Co. produced 1,776,678 oz. silver against 2,714,766 oz. in 1912. Costs increased from 14.027 to 23c. per ounce during the period. This Company controls about 66% of the Porcupine Crown, at Porcupine, which produced gold netting \$235,000 in 1913. Costs were \$7.75 per ton. Ore reserves are estimated at \$1,923,000. A great deal of interest is being taken in the Munro goldfield, east of Matheson.

A fire at Porcupine on January 29 did damage amounting to \$7000. The Hollinger mill treated 12,657 tons of ore averaging \$16 per ton during December, with 96.3% recovery. Gross profits were \$114,249. Costs totaled \$5,964 per ton. The annual report of the Hollinger Gold Mines Co. shows that 138,291 tons of ore was treated in 1913, yielding \$2,471,273. Operating expenses were \$843,159; dividends, \$1,170,000; and surplus, \$458,113. Ore reserves total 845,309 tons, worth \$11,604,000, against 644,540 tons, worth \$11,271,400, in 1912.

Ore worth \$175 per ton has been sent from the Porphyry

Hill mine to Perth Anboy, New Jersey. From 14 to 16 in. of ore is being mined at a depth of 45 feet.

The Dome mill, at Porcupine, treated 560 tons of ore during one day of the last week in January. Good progress is being made on the additional 40 stamps and treatment plant. In new ground, the diamond-drill working on the 425-ft. level has cut two new shoots in the Hollinger mine. The ore is of good width and grade. Two new air-compressors have been ordered. Thirty-eight machine-drills are used at present. There will be an air-chamber underground for the new plant. The additional 20 stamps are being steadily erected.

YUKON

The mining recorder at Mayo states that the district is promising. A Keystone drill is still working at Duncan in hard gravel. The silver properties open well, and the first load of ore has been delivered at Mayo. The owners intend shipping 100 tons this winter to go out to a smelter in the spring. The galena ore has given assays from 144 to 1327 oz. per ton.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for January 1914:

| | |
|--------------------------|----------|
| Stamps working | 40 |
| Time, days | 29½ |
| Ore crushed, tons | 5940 |
| Total recovery | \$52,067 |
| Operating expenses | 20,000 |
| Net earnings | 32,067 |

The Oriental Consolidated company's January output was \$141,225, against \$142,980 in December. During the latter month there was a shortage of water at the Tabowie and Kuk San Dong mills, and interruptions to the power service.

MEXICO

CHIHUAHUA

Owing to the revolution, neither the Dolores nor El Rayo mine, owned by the Mines Company of America, is in operation.

HIDALGO

The Santa Gertrudis mill treated 32,187 tons of ore in December, yielding a profit of \$92,000.

SONORA

An important mining ruling in Mexico is that of the 'Constitutional' department of mines, which became effective January 16. It was issued in all territory under rebel control. By virtue of this order, claim-owners can obtain temporary title, guaranteed by the rebel government in any portion of the country under their control. Later, when the rebels have the entire country under control, the edict states, permanent titles will be issued.

It is stated that the old Mulatos mine, in the Sahuaripa district, has been sold to Boston people for a large sum. The Mines Company of America has only the Creston-Colo-rado and Grand Central mines in operation. La Dura is shut down. The Grand Central was bought in October 1913, and produces gold and silver ore worth \$6 to \$7 per ton. During the period of January 1 to September 30, 1913, the Company's revenue was \$1,560,768, and net profit \$461,847. Dividends amounted to \$210,256, and the surplus at the end of September was \$2,656,179.

The Lampazos mine, situated 40 miles south of Moctezuma, has been sold to Epes Randolph and associates of Tucson, Arizona, by the Bank of Sonora. This property is one of the *antiguas* of this state, and includes several claims, the most important being Los Tajos. There are large tonnages of high-grade ore, but the lower grade of silver ore will be treated by cyaniding. Machinery for the Nacozari Consolidated concentrating plant has arrived and is now being erected. El Temblor mill is working steadily.

Personal

D. C. JACKLING is in New York.

R. C. TROEGER is at Los Angeles.

W. H. ALDRIDGE is in the West.

CHARLES C. SELBIE has gone to Africa.

E. B. BRADEN is back from New York.

S. H. BRADY was in San Francisco Tuesday.

F. L. GRAMMER was in New York last week.

R. M. ATWATER, Jr., has returned from Europe.

J. CLAUDE JONES was in San Francisco Saturday.

BRAXTON BIGELOW has left New York for Morococha.

S. S. SORENSEN is now manager for the Braden Copper Company.

LESTER W. STRAUSS is visiting various mining districts in Chile.

T. A. RICKARD has been lecturing at the Royal School of Mines.

FREDERICK G. FARISH has left Sneffels, Colorado, and is in Denver.

KARL EILERS was in San Francisco last week, and has gone to Arizona.

C. B. WHITWELL is examining mining property in Kern county, California.

R. T. WHITE has returned to the United States from Chile by way of Europe.

NEWTON CLEAVELAND's office is now at 623 Insurance building, San Francisco.

ARCHER E. WHEELER has sailed for Europe to take up his work at Tanganyika.

H. C. BELLINGER expects to return from the Great Cobar to New York early in April.

G. J. SIELAFF has been appointed general manager for the Abangarez Gold Fields of Costa Rica.

ELI T. CONNER has removed to Room 1315, Stephen Girard building, 12th street, Philadelphia, Pennsylvania.

W. M. HENDERSON SCOTT has gone to Central America in connection with properties owned by the Breitung Mines Corporation.

H. W. HARDINGE has left New York for a six weeks' tour of the West, visiting practically all of the mining centres before he returns.

F. N. WATTS, mill superintendent at the Black Oak mine, Tuolumne county, California, is visiting the cyaniding and milling plants and mines at Grass Valley.

CECIL POCKOCK has left Peru on six months' leave, and is making a trip through the United States and Europe. On February 3 he was married in Lima, Peru, to Miss Gwen Sutton-Flack, of London. His address until July, will be 892 Avenue C, Bayonne, New Jersey.

The annual report of the Portland Gold Mining Co., of Cripple Creek, Colorado, gives the following names as members of the staff: manager of mines at Victor, Frank L. Smale; mining engineer, Fred Jones; master mechanic at mines, L. E. Flamboe; general manager of milling department, George M. Taylor; at Colorado Springs mill, superintendent, James B. Heffernan; assistant, J. M. Tippet; constructing engineer, S. J. Connolly; master mechanic, P. Kalaher; at Victor mill, superintendent, Thomas B. Crowe; assistant, L. W. Lennox; and master mechanic, W. W. Lawhead. The consulting engineers and metallurgists are Hills & Willis, and the Merrill Metallurgical Co., respectively.

San Francisco members of the Mining and Metallurgical Society met at dinner February 12.

Writing on January 29, Samuel Montagu & Co. state that the main strength of the silver market continues to be the covering of sales as they fall due; but the rather better undertone that was felt this week accelerated the inclination of 'bear' operators to close their commitments. The holdings of silver in Shanghai, by banks and others, consist of £5,380,000 in cycee or currency, and of £180,000 in bars. A shipment of silver worth £8000 was made from San Francisco to Hongkong.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

The first week of each month is nearly always characterized by an inactive copper market, both buyers and sellers waiting for the Copper Producers' report. Speculation is always rife as to what it will show, and for this month guesses ranged from 10,000,000 to 20,000,000 lb. increase in stocks. Early last week the agencies made good sales at 14 1/2c., but the demand was not sharp. Buying fell off at the end of the week, reflecting a fall of £1 per ton for standard on the London exchange. Exports from February 1 to 5 were 6448 tons, as

compared with 8445 tons in the same period last year. The period is too short for an accurate comparison, however.

QUICKSILVER
